# Uncountable Automatic Classes and Learning 

Sanjay Jain, Qinglong Luo ${ }^{\dagger}$ Pavel Semukhin ${ }^{\ddagger}$ and Frank Stephan ${ }^{\S}$

#### Abstract

In this paper we consider uncountable classes recognizable by $\omega$-automata and investigate suitable learning paradigms for them. In particular, the counterparts of explanatory, vacillatory and behaviourally correct learning are introduced for this setting. Here the learner reads in parallel the data of a text for a language $L$ from the class plus an $\omega$-index $\alpha$ and outputs a sequence of $\omega$-automata such that all but finitely many of these $\omega$-automata accept the index $\alpha$ if and only if $\alpha$ is an index for $L$.

It is shown that any class is behaviourally correct learnable if and only if it satisfies Angluin's tell-tale condition. For explanatory learning, such a result needs that a suitable indexing of the class is chosen. On the one hand, every class satisfying Angluin's tell-tale condition is vacillatorily learnable in every indexing; on the other hand, there is a fixed class such that the level of the class in the hierarchy of vacillatory learning depends on the indexing of the class chosen.

We also consider a notion of blind learning. On the one hand, a class is blind explanatorily (vacillatorily) learnable if and only if it satisfies Angluin's tell-tale condition and is countable; on the other hand, for behaviourally correct learning, there is no difference between the blind and non-blind version.

This work establishes a bridge between the theory of $\omega$-automata and inductive inference (learning theory).

## 1 Introduction

Usually, in learning theory one considers classes consisting of countably many languages from some countable domain. A typical example here is the class of all recursive subsets of $\{0,1,2\}^{*}$, where $\{0,1,2\}^{*}$ is the set of all finite strings over the alphabet $\{0,1,2\}$. However, each countably infinite domain has uncountably many subsets, and thus we miss out many potential targets when we consider only countable classes. The main goal of this paper is to

[^0]find a generalization of the classical model of learning which would be suitable for working with uncountable classes of languages. The classes which we consider can be uncountable, but they still have some structure, namely, they are recognizable by Büchi automata. We will investigate, how the classical notions of learnability have to be adjusted in this setting in order to obtain meaningful results. To explain our approach in more detail, we first give an overview of the classical model of inductive inference which is the underlying model of learning in our paper.

Consider a class $\mathcal{L}=\left\{L_{i}\right\}_{i \in I}$, where each language $L_{i}$ is a subset of $\Sigma^{*}$, the set of finite strings over an alphabet $\Sigma$. In a classical model of learning, which was introduced and studied by Gold [9], a learner $M$ receives a sequence of all the strings from a given language $L \in \mathcal{L}$, possibly with repetitions. Such a sequence is called a text for the language. After reading the first $n$ strings from the texts, the learner outputs a hypothesis $i_{n}$ about what the target language might be. The learner succeeds if it eventually converges to an index that correctly describes the language to be learnt, that is, if $\lim _{n} i_{n}=i$ and $L=L_{i}$. If the learner succeeds on all texts for all languages from a class, then we say that it learns this class. This is the notion of explanatory learning (Ex). Such a model became the standard one for the learnability of countable classes. Besides Ex, several other paradigms for learning have been considered like, e.g., behaviourally correct (BC) learning [3], vacillatory or finite explanatory (FEx) learning [8], partial identification (Part) [13] and so on.

The indices that the learner outputs are usually finite objects like natural numbers or finite strings. For example, Angluin [1] initiated the research on learnability of uniformly recursive families indexed by natural numbers, and, in recent work, Jain, Luo and Stephan [10] considered automatic indexings by finite strings in place of uniformly recursive indexings. The collection of such finite indices is countable, and hence we can talk only about countable classes of languages. On the other hand, the collection of all the subsets of $\Sigma^{*}$ is uncountable, and it looks too restrictive to consider only countable classes. Because of this, it is interesting to find a generalization of the classical model which will allow us to study the learnability of uncountable classes.

Below is an informal description of the learning model that we investigate in this paper. First, since we are going to work with uncountable classes, we need uncountably many indices to index a class to be learnt. For this purpose we will use infinite strings (or $\omega$-strings) over a finite alphabet. Next, we want such indexings to be effective or "computable" in some sense. There are computing machines, called Büchi automata or $\omega$-automata, which can be used naturally for processing $\omega$-strings. They were first introduced by Büchi $[6,7]$ to prove the decidability of S1S, the monadic second-order theory of the natural numbers with successor function $S(x)=x+1$. Because of this and other decidability results, the theory of $\omega$-automata has become a popular area of research in theoretical computer science (see, e.g., [14]). Taking these points into account, we will assume that a class to be learnt has an indexing by $\omega$-strings which is Büchi recognizable.

The main difference between our model of learning and the classical one is that the learner does not output hypotheses as it processes a text. The reason for this is that it is not possible to output an arbitrary infinite string in a finite amount of time. Instead, in our model, the learner is presented with an index $\alpha$ and a text $T$, and it must decide whether $T$ is a text for the set with the index $\alpha$. During its work, the learner outputs an infinite sequence of Büchi automata $\left\{A_{n}\right\}_{n \in \omega}$ (where $\omega$ denotes the set of natural numbers) such that $A_{n}$ accepts the
index $\alpha$ if and only if the learner at stage $n$ thinks that $T$ is indeed a text for the set with the index $\alpha$. The goal of the learner is to converge in the limit to the right answer.

As one can see from the description above, the outputs of a learner take the form of $\omega$-automata instead of just binary answers 'yes' or 'no'. We chose such definition due to the fact that a learner can read only a finite part of an infinite index in a finite amount of time. If we required that a learner outputs its 'yes' or 'no' answer based on such finite information, then our model would become too restrictive. On the other hand, a Büchi automaton allows a learner to encode additional infinitary conditions that have to be verified before the index will be accepted or rejected, for example, if the index contains infinitely many 1's or not. This approach makes a learner more powerful, and more nontrivial classes become learnable.

Probably the most interesting property of our model is that for many learning criteria, the learnability coincides with Angluin's classical tell-tale condition for the countable case (see the table at the end of this section). Angluin's condition states that for every set $L$ from a class $\mathcal{L}$, there is a finite subset $D_{L} \subseteq L$ such that for any other $L^{\prime} \in \mathcal{L}$ with $D_{L} \subseteq L^{\prime} \subseteq L$ we have that $L^{\prime}=L$. It is also well-known that in the classical case, every r.e. class is learnable according to the criterion of partial identification [13]. We will show that in our model every $\omega$-automatic class can be learnt according to this criterion.

The results described above suggest that the notions defined in this paper match the intuition of learnability, and that our model is a natural one suitable for investigating the learnability of uncountable classes of languages.

We also consider a notion of blind learning. A learner is called blind if it does not see an index presented to it. Such a learner can see only an input text, but nevertheless it must decide whether the index and the text represent the same language. It turns out that for the criterion of behaviourally correct learning, the blind learners are as powerful as the non-blind ones, but for the other learning criteria this notion becomes more restrictive.

The reader can find all formal definitions of the notions discussed here and some necessary preliminaries in the next section. We summarize our results:

| Criterion | Condition | Indexing | Theorems |
| :--- | :--- | :---: | :---: |
| Ex | ATTC | New | $4.1,5.3$ |
| FEx | ATTC | Original | $3.1,5.3$ |
| BC | ATTC | Original | 5.3 |
| Part | Any class | Original | 6.1 |
| BlindBC | ATTC | Original | $5.1,5.3$ |
| BlindEx | ATTC \& Countable | Original | 5.2 |
| BlindFEx | ATTC \& Countable | Original | 5.2 |
| BlindPart | Countable | Original | 6.2 |

In this table, the first column lists the learning criteria that we studied. Here, Ex stands for explanatory learning, BC for behaviourally correct learning, FEx for finite explanatory or vacillatory learning, and Part for partial identification. A prefix Blind denotes the blind version of the corresponding criterion. The second column describes equivalent conditions that an automatic class must satisfy for being learnable under the given learning criterion of the first column. Here, ATTC means that the class must satisfy Angluin's tell-tale condition, and Countable means that the class must be countable. The next column indicates whether
the learner uses the original indexing of the class or a new one. The last column gives a reference to a theorem/corollary where the result is proved.

## 2 Preliminaries

An $\omega$-automaton is essentially a finite automaton operating on $\omega$-strings with an infinitary acceptance condition which decides - depending upon the infinitely often visited nodes which $\omega$-strings are accepted and which are rejected. For a general background on the theory of finite automata the reader is referred to [11].

Definition 2.1 (Büchi $[6,7]$ ). A nondeterministic $\omega$-automaton is a tuple $A=(S, \Sigma, I, T)$, where
(a) $S$ is a finite set of states,
(b) $\Sigma$ is a finite alphabet,
(c) $I \subseteq S$ is the set of initial states, and
(d) $T$ is the transition function $T: S \times \Sigma \rightarrow \mathcal{P}(S)$, where $\mathcal{P}(S)$ is the power set of $S$.

An automaton $A$ is deterministic if and only if $|I|=1$, and for all $s \in S$ and $a \in \Sigma$, $|T(s, a)|=1$.

An $\omega$-string over an alphabet $\Sigma$ is a function $\alpha: \omega \rightarrow \Sigma$, where $\omega$ is the set of natural numbers. We often identify an $\omega$-string with the infinite sequence $\alpha=\alpha_{0} \alpha_{1} \alpha_{2} \ldots$, where $\alpha_{i}=\alpha(i)$. Let $\Sigma^{*}$ and $\Sigma^{\omega}$ denote the set of all finite strings and the set of all $\omega$-strings over the alphabet $\Sigma$, respectively.

We always assume that the elements of an alphabet $\Sigma$ are linearly ordered. This order can be extended to the length-lexicographical order $\leq_{l l e x}$ on $\Sigma^{*}$; here $x \leq_{l l e x} y$ if and only if $|x|<|y|$ or $|x|=|y| \wedge x \leq_{l e x} y$, where $\leq_{l e x}$ is the standard lexicographical order.

Given an $\omega$-automaton $A=(S, \Sigma, I, T)$ and an $\omega$-string $\alpha$, a run of $A$ on $\alpha$ is an $\omega$-string

$$
r=s_{0} \ldots s_{n} s_{n+1} \ldots \in S^{\omega}
$$

such that $s_{0} \in I$ and for all $n, s_{n+1} \in T\left(s_{n}, \alpha_{n}\right)$. Note that if an $\omega$-automaton $A$ is deterministic, then for every $\alpha$, there is a unique run of $A$ on $\alpha$. In this case we will use the notation $S t_{A}(\alpha, k)$ to denote the state of $A$ after it has read the first $k$ symbols of $\alpha$.

Definition 2.2. Let $\operatorname{Inf}(r)$ denote the infinity set of a run $r$, that is,

$$
\operatorname{Inf}(r)=\{s \in S: s \text { appears infinitely often in } r\} .
$$

We define the following accepting conditions for the run $r$ :

1) Büchi condition is determined by a subset $F \subseteq S$. The run $r$ is accepting if and only if $\operatorname{Inf}(r) \cap F \neq \emptyset$.
2) Muller condition is determined by a subset $\mathcal{F} \subseteq \mathcal{P}(S)$. The run $r$ is accepting if and only if $\operatorname{Inf}(r) \in \mathcal{F}$.
3) Rabin condition is determined by $\Omega=\left\{\left(F_{1}, G_{1}\right), \ldots,\left(F_{h}, G_{h}\right)\right\}$, where all $F_{i}$ and $G_{i}$ are subsets of $S$. The run $r$ is accepting if and only if there is an $i$ such that $1 \leq i \leq h$, $\operatorname{Inf}(r) \cap F_{i} \neq \emptyset$ and $\operatorname{Inf}(r) \cap G_{i}=\emptyset$.

It can be shown that all these acceptance conditions are equivalent in the sense that if a language is accepted by an automaton according to one of the above acceptance criteria, it can also be accepted by an automaton according to any other of these criteria (see [11]). Therefore, we assume that we have fixed one of the acceptance conditions defined above and say that an $\omega$-automaton $A$ accepts a string $\alpha$ if and only if there is a run of $A$ on $\alpha$ that satisfies this condition. Let $L(A)$ denote the set of strings accepted by an automaton $A$ according to the chosen acceptance condition.

Furthermore, every $\omega$-automaton is equivalent to a deterministic one with Muller acceptance condition (again, see [11]). Thus, if not explicitly stated otherwise, by an automaton we will always mean a deterministic $\omega$-automaton with Muller acceptance condition.

Definition 2.3 (Khoussainov and Nerode [11, 12]). 1) A finite automaton is a tuple $A=$ $(S, \Sigma, I, T, F)$, where $S, \Sigma, I$ and $T$ are the same as in the definition of an $\omega$-automaton, and $F \subseteq S$ is the set of final states.
2) For a finite string $w=a_{0} \ldots a_{n-1} \in \Sigma^{*}$, a run of $A$ on $w$ is a sequence $s_{0} \ldots s_{n} \in S^{*}$ such that $s_{0} \in I$ and $s_{i+1} \in T\left(s_{i}, a_{i}\right)$ for all $i \leq n-1$. The run is accepting if and only if $s_{n} \in F$. The string $w=a_{0} \ldots a_{n-1}$ is accepted by $A$ if and only if there is an accepting run of $A$ on $w$.

Definition 2.4.1) A convolution of $k \omega$-strings $\alpha_{1}, \ldots, \alpha_{k} \in \Sigma^{\omega}$ is an $\omega$-string $\otimes\left(\alpha_{1}, \ldots, \alpha_{k}\right)$ over the alphabet $\Sigma^{k}$ defined as

$$
\otimes\left(\alpha_{1}, \ldots, \alpha_{k}\right)(n)=\left(\alpha_{1}(n), \ldots, \alpha_{k}(n)\right) \text { for every } n \in \omega
$$

2) A convolution of $k$ finite strings $w_{1}, \ldots, w_{k} \in \Sigma^{*}$ is a string $\otimes\left(w_{1}, \ldots, w_{k}\right)$ of length $l=$ $\max \left\{\left|w_{1}\right|, \ldots,\left|w_{k}\right|\right\}$ over the alphabet $(\Sigma \cup\{\#\})^{k}$, where $\#$ is a new padding symbol, defined as

$$
\otimes\left(w_{1}, \ldots, w_{k}\right)(n)=\left(v_{1}(n), \ldots, v_{k}(n)\right) \text { for every } n<l
$$

where for each $i=1, \ldots, k$ and $n<l$,

$$
v_{i}(n)= \begin{cases}w_{i}(n) & \text { if } n<\left|w_{i}\right| \\ \# & \text { otherwise }\end{cases}
$$

3) Correspondingly one defines the convolution of finite strings and $\omega$-strings: one identifies each finite string $\sigma$ with the $\omega$-string $\sigma \#^{\omega}$ and forms then the corresponding convolution of $\omega$-strings.
4) A convolution of $k$-ary relation $R$ on finite or $\omega$-strings is defined as

$$
\otimes R=\left\{\otimes\left(x_{1}, \ldots, x_{k}\right):\left(x_{1}, \ldots, x_{k}\right) \in R\right\} .
$$

5) A relation $R$ on finite or $\omega$-strings is automatic if and only if its convolution $\otimes R$ is recognizable by a finite or an $\omega$-automaton, respectively.

For the ease of notation, we often just write $(x, y)$ instead of $\otimes(x, y)$ and so on. It is well-known that the automatic relations are closed under union, intersection, projection and complementation. In general, the following theorem holds, which we will often use in this paper.

Theorem 2.5 (Blumensath and Grädel $[4,5]$ ). If a relation $R$ on $\omega$-strings is definable from other automatic relations $R_{1}, \ldots, R_{k}$ by a first-order formula, then $R$ itself is automatic.

Remark 2.6. 1) If we use additional parameters in a first-order definition of a relation $R$, then these parameters must be ultimately periodic strings.
2) Furthermore, in a definition of a relation $R$ we can use first-order variables of two sorts, namely, one ranging over $\omega$-strings and one ranging over finite strings. We can do this because every finite string $v$ can be identified with its $\omega$-expansion $v \#^{\omega}$, and the set of all $\omega$-expansions of the finite strings over alphabet $\Sigma$ is automatic.

A class $\mathcal{L}$ is a collection of sets of finite strings over some alphabet $\Gamma$, i.e., $\mathcal{L} \subseteq \mathcal{P}\left(\Gamma^{*}\right)$. An indexing for a class $\mathcal{L}$ is an onto mapping $f: I \rightarrow \mathcal{L}$, where $I$ is the set of indices. We will often denote the indexing as $\left\{L_{\alpha}\right\}_{\alpha \in I}$, where $L_{\alpha}=f(\alpha)$.

An indexing $\left\{L_{\alpha}\right\}_{\alpha \in I}$ is automatic if and only if $I$ is an automatic subset of $\Sigma^{\omega}$ for some alphabet $\Sigma$ and the relation $\left\{(x, \alpha): x \in L_{\alpha}\right\}$ is automatic. A class is automatic if and only if it has an automatic indexing. If it is not stated otherwise, all indexings and all classes considered herein are assumed to be automatic.

Remark 2.7. According to the definition, an automatic class always comes with an automatic indexing. However we will often say just an "automatic class" instead of an "automatic class with a given automatic indexing." Such abbreviation makes sense because many results of the paper do not depend on the particular choice of an indexing for a class. This can be seen from the table in the introduction section that summarizes the main results. The fact that a learner uses the original indexing of the class actually means that the choice of such indexing is not important. In some cases, where an indexing is important, it will be mentioned explicitly.

Example 2.8. Here are some examples of automatic classes:

1) the class of all open intervals $I=\{q \in \mathbb{D}: p<q<r\}$ of dyadic rationals where the border points $p$ and $r$ can be any real numbers;
2) the class of such intervals where $r-p$ is equal to 1 or 2 or 3 ;
3) the class of all sets of finite strings which are given as the prefixes of an infinite sequence;
4) the class of all sets of natural numbers in unary coding.

On the other hand, the class of all finite sets of strings over the alphabet $\{0,1\}$ is not automatic.

A text is an $\omega$-string $T$ of the form

$$
T=u_{0}, u_{1}, u_{2}, \ldots
$$

such that each $u_{i}$ is either equal to the pause symbol \# or belongs to $\Gamma^{*}$, where $\Gamma$ is some alphabet. Note that the comma "," is also part of the text and servers as a delimiter for $u_{i}$ 's. We call $u_{i}$ the $i$-th input of the text. The content of a text $T$ is the set content $(T)=$ $\left\{u_{i}: u_{i} \neq \#\right\}$. If $\operatorname{content}(T)$ is equal to a set $L \subseteq \Gamma^{*}$, then we say that $T$ is a text for $L$. A canonical text for an infinite set $L$ is the listing of all the strings from $L$ in lengthlexicographical order. A canonical text for a finite set $L$ starts with the listing of all the strings from $L$ in length-lexicographical order, and ends in $\#^{\omega}$.

Definition 2.9. Let $\Gamma$ and $\Sigma$ be alphabets for sets and indices, respectively. A learner is a Turing machine $\mathcal{M}$ that has the following:

1) two read-only tapes: one for an $\omega$-string from $\Sigma^{\omega}$ representing an index and one for a text for a set $L \subseteq \Gamma^{*}$;
2) one write-only output tape on which $\mathcal{M}$ writes a sequence of automata (in a suitable coding);
3) one read-write working tape.

Let $\operatorname{Ind}(\mathcal{M}, \alpha, T, s)$ and $\operatorname{Txt}(\mathcal{M}, \alpha, T, s)$ denote the number of symbols read in the index and text tapes by learner $\mathcal{M}$ up to step $s$ when it processes an index $\alpha$ and a text $T$. Without loss of generality, we will assume that

$$
\lim _{s \rightarrow \infty} \operatorname{Ind}(\mathcal{M}, \alpha, T, s)=\lim _{s \rightarrow \infty} \operatorname{Txt}(\mathcal{M}, \alpha, T, s)=\infty
$$

for any $\alpha$ and $T$. By $\mathcal{M}(\alpha, T, k)$ we denote the $k$-th automaton output by learner $\mathcal{M}$ when processing an index $\alpha$ and a text $T$. Without loss of generality, for the learning criteria considered in this paper, we assume that $\mathcal{M}(\alpha, T, k)$ is defined for all $k$.

Definition 2.10 (Based on $[3,8,9,13])$. Let a class $\mathcal{L}=\left\{L_{\alpha}\right\}_{\alpha \in I}$ (together with its indexing) and a learner $\mathcal{M}$ be given. We say that

1) $\mathcal{M} \mathbf{B C}$-learns $\mathcal{L}$ if and only if for any index $\alpha \in I$ and any text $T$ with $\operatorname{content}(T) \in \mathcal{L}$, there exists $n$ such that for every $m \geq n$,

$$
\mathcal{M}(\alpha, T, m) \text { accepts } \alpha \quad \text { if and only if } \quad L_{\alpha}=\operatorname{content}(T)
$$

2) $\mathcal{M}$ Ex-learns $\mathcal{L}$ if and only if for any index $\alpha \in I$ and any text $T$ with content $(T) \in \mathcal{L}$, there exists $n$ such that for every $m \geq n, \mathcal{M}(\alpha, T, m)=\mathcal{M}(\alpha, T, n)$ and

$$
\mathcal{M}(\alpha, T, m) \text { accepts } \alpha \quad \text { if and only if } \quad L_{\alpha}=\operatorname{content}(T) .
$$

3) $\mathcal{M}$ FEx-learns $\mathcal{L}$ if and only if $\mathcal{M}$ BC-learns $\mathcal{L}$ and for any $\alpha \in I$ and any text $T$ with content $(T) \in \mathcal{L}$, the set $\{\mathcal{M}(\alpha, T, n): n \in \omega\}$ is finite.
4) $\mathcal{M} \mathbf{F E x}{ }_{k}$-learns $\mathcal{L}$ if and only if $\mathcal{M} \mathbf{B C}$-learns $\mathcal{L}$ and for any $\alpha \in I$ and any text $T$ with content $(T) \in \mathcal{L}$, there exists $n$ such that

$$
|\{\mathcal{M}(\alpha, T, m): m \geq n\}| \leq k
$$

5) $\mathcal{M}$ Part-learns $\mathcal{L}$ if and only if for any $\alpha \in I$ and any $T$ with $\operatorname{content}(T) \in \mathcal{L}$, there exists a unique automaton $A$ such that for infinitely many $m, \mathcal{M}(\alpha, T, m)=A$, and for this unique $A$,
$A$ accepts $\alpha$ if and only if $L_{\alpha}=\operatorname{content}(T)$.
Here the abbreviations BC, Ex, FEx and Part stand for 'behaviourally correct', 'explanatory', 'finite explanatory' and 'partial identification', respectively; 'finite explanatory learning' is also called 'vacillatory learning'. We will also use the notations BC, Ex, FEx, $\mathbf{F E x}_{k}$ and Part to denote the collection of classes (with corresponding indexings) that are BC-, Ex-, FEx-, $\mathbf{F E x}_{k^{-}}$and Part-learnable, respectively.

Definition 2.11. A learner is called blind if it does not see the tape which contains an index. The classes that are blind BC-, Ex-, etc. learnable are denoted as BlindBC, BlindEx, etc., respectively.

Definition 2.12 (Angluin [1]). We say that a class $\mathcal{L}$ satisfies Angluin's tell-tale condition if and only if for every $L \in \mathcal{L}$ there is a finite $D_{L} \subseteq L$ such that for every $L^{\prime} \in \mathcal{L}$, if $D_{L} \subseteq L^{\prime} \subseteq L$ then $L^{\prime}=L$. Such $D_{L}$ is called a tell-tale set for $L$.

Using techniques similar to those that were introduced in [1], it can be shown that
Fact 2.13. If a class $\mathcal{L}$ is $\mathbf{B C}$-learnable, then $\mathcal{L}$ satisfies Angluin's tell-tale condition.
The converse will also be shown to be true, hence for automatic classes one can equate " $\mathcal{L}$ is learnable" with " $\mathcal{L}$ satisfies Angluin's tell-tale condition". Note that the second and the third class given in Example 2.8 satisfy Angluin's tell-tale condition.

## 3 Vacillatory Learning

In the following it is shown that every learnable class can even be vacillatorily learnt and that the corresponding FEx-learner uses overall on all possible inputs only a fixed number of automata.

Theorem 3.1. Let $\left\{L_{\alpha}\right\}_{\alpha \in I}$ be a class that satisfies Angluin's tell-tale condition. Then there are finitely many automata $A_{1}, \ldots, A_{c}$ and an $\mathbf{F E x}$-learner $\mathcal{M}$ for the class $\left\{L_{\alpha}\right\}_{\alpha \in I}$ with the property that for any $\alpha \in I$ and any text $T$ for a set from $\left\{L_{\alpha}\right\}_{\alpha \in I}$, the learner $\mathcal{M}$ oscillates only between some of the automata $A_{1}, \ldots, A_{c}$ on $\alpha$ and $T$.

Proof. Let $M$ be a deterministic automaton recognizing the relation $\left\{(x, \alpha): x \in L_{\alpha}\right\}$, and let $N$ be a deterministic automaton recognizing

$$
\left\{(x, \alpha):\left\{y \in L_{\alpha}: y \leq_{l l e x} x\right\} \text { is a tell-tale for } L_{\alpha}\right\}
$$

Such an $N$ exists since the relation is first-order definable from ' $x \in L_{\alpha}$ ' and $\leq_{l l e x}$ by the formula:

$$
\begin{aligned}
N \text { accepts }(x, \alpha) \Longleftrightarrow & \forall \alpha^{\prime} \in I\left(\text { if } \forall y\left(\left(y \in L_{\alpha} \& y \leq_{l l e x} x\right) \rightarrow y \in L_{\alpha^{\prime}}\right) \&\right. \\
& \left.\forall y\left(y \in L_{\alpha^{\prime}} \rightarrow y \in L_{\alpha}\right), \text { then } \forall y\left(y \in L_{\alpha^{\prime}} \leftrightarrow y \in L_{\alpha}\right)\right) .
\end{aligned}
$$

For each $\alpha \in I$, consider an equivalence relation $\equiv_{M, \alpha}$ defined as

$$
\begin{aligned}
& x \equiv_{M, \alpha} y \Longleftrightarrow \quad \text { there is a } t>\max \{|x|,|y|\} \text { such that } \\
& \operatorname{St}_{M}(\otimes(x, \alpha), t)=S t_{M}(\otimes(y, \alpha), t) .
\end{aligned}
$$

An equivalence relation $\equiv_{N, \alpha}$ is defined in a similar way.
Note that the number of the equivalence classes of $\equiv_{M, \alpha}$ and $\equiv_{N, \alpha}$ are bounded by the number of states of $M$ and $N$, respectively. Also, for every $x, y$, if $x \equiv_{M, \alpha} y$ then $x \in L_{\alpha} \leftrightarrow$ $y \in L_{\alpha}$. Therefore, $L_{\alpha}$ is the union of finitely many equivalence classes of $\equiv_{M, \alpha}$.

Let $m$ and $n$ be the number of states of $M$ and $N$, respectively. Consider the set of all finite tables $U=\left\{U_{i, j}: 1 \leq i \leq m, 1 \leq j \leq n\right\}$ of size $m \times n$ such that each $U_{i, j}$ is either equal to a subset of $\{1, \ldots, i\}$ or to a special symbol Reject. Note that the number of such tables is finite.

With each such table $U$ we will associate an automaton $A$ as described below. The algorithm for learning $\left\{L_{\alpha}\right\}_{\alpha \in I}$ is now roughly as follows. On every step, the learner $\mathcal{M}$ reads a finite part of the input text and the index and based on this information constructs a table $U$. After that $\mathcal{M}$ outputs the automaton associated with $U$.

First, we describe the construction of an automaton $A$ for each table $U$. For every $\alpha \in I$, let $m(\alpha)$ and $n(\alpha)$ be the numbers of the equivalence classes of $\equiv_{M, \alpha}$ and $\equiv_{N, \alpha}$, respectively. Also, let

$$
x_{1}<_{\text {llex }} \cdots<_{\text {llex }} \quad x_{m(\alpha)}
$$

be the length-lexicographically least representatives of the equivalence classes of $\equiv_{M, \alpha}$. Our goal is to construct $A$ such that

$$
\begin{aligned}
A \text { accepts } \alpha \Longleftrightarrow & U_{m(\alpha), n(\alpha)} \text { is a subset of }\{1, \ldots, m(\alpha)\}, \text { and } L_{\alpha} \text { is equal } \\
& \text { to the union of the } \equiv_{M, \alpha} \text {-equivalence classes that are } \\
& \text { represented by } x_{i} \text { 's with } i \in U_{m(\alpha), n(\alpha)} .
\end{aligned}
$$

Let $E q S t_{M}(\alpha, x, y, z)$ be the relation defined as

$$
E q S t_{M}(\alpha, x, y, z) \quad \Longleftrightarrow \quad S t_{M}(\otimes(x, \alpha),|z|)=S t_{M}(\otimes(y, \alpha),|z|)
$$

The relation $E q S t_{N}(\alpha, x, y, z)$ is defined similarly. Note that these relations are automatic.
Instead of constructing $A$ explicitly, we will show that the language which $A$ needs to recognize is first-order definable from $E q S t_{M}(\alpha, x, y, z), E q S t_{N}(\alpha, x, y, z)$ and the relations recognized by $M$ and $N$.

First, note that the equivalence relation $x \equiv_{M, \alpha} y$ can be defined by a formula:

$$
\exists z\left(|z|>\max \{|x|,|y|\} \text { and } E q S t_{M}(\alpha, x, y, z)\right) .
$$

Similarly one can define $x \equiv_{N, \alpha} y$. The fact that $\equiv_{M, \alpha}$ has exactly $k$ many equivalence classes can be expressed by a formula:

$$
\operatorname{ClNum}_{M, k}(\alpha)=\exists x_{1} \ldots \exists x_{k}\left(\bigwedge_{1 \leq i<j \leq k} x_{i} \not \equiv_{M, \alpha} x_{j} \& \forall y \bigvee_{1 \leq i \leq k} y \equiv_{M, \alpha} x_{i}\right)
$$

Again, ClNum $_{N, k}(\alpha)$ expresses the same fact for $\equiv_{N, \alpha}$. Finally, the fact that $A$ accepts $\alpha$ can be expressed by the following first-order formula:

$$
\begin{aligned}
& \bigvee_{(i, j): U_{i, j} \neq \operatorname{Reject}}\left(\operatorname { C l N u m } _ { M , i } ( \alpha ) \& \operatorname { C l N u m } _ { N , j } ( \alpha ) \& \exists x _ { 1 } \ldots \exists x _ { i } \left(x_{1}<_{l l e x} \cdots<_{l l e x} x_{i} \&\right.\right. \\
&\left.\left.\forall z\left(z \in L_{\alpha} \leftrightarrow \bigvee_{k \in U_{i, j}} z \equiv_{M, \alpha} x_{k}\right) \& \bigwedge_{1 \leq k \leq i} \forall y\left(y<_{l l e x} x_{k} \rightarrow y \not \equiv_{M, \alpha} x_{k}\right)\right)\right) .
\end{aligned}
$$

We now describe the algorithm for learning the class $\left\{L_{\alpha}\right\}_{\alpha \in I}$. We will use the notation $x \equiv_{M, \alpha, s} y$ as an abbreviation of
"there is $t$ such that $s \geq t>\max \{|x|,|y|\}$ and $S t_{M}(\otimes(x, \alpha), t)=S t_{M}(\otimes(y, \alpha), t)$."
As before, let $m$ and $n$ be the numbers of states of automata $M$ and $N$, respectively. At step $s, \mathcal{M}$ computes $\leq_{l l e x}$ least representatives of the equivalence classes of $\equiv_{M, \alpha, s}$ and $\equiv_{N, \alpha, s}$ on the strings with length shorter than $s$. In other words, it computes $x_{1}, \ldots, x_{p}$ and $y_{1}, \ldots, y_{q}$ such that
a) $x_{1}$ is the empty string,
b) $x_{k+1}$ is the $\leq_{l l e x}$ least $x>_{l l e x} x_{k}$ such that $|x| \leq s$ and $x \not \equiv_{M, \alpha, s} x_{i}$ for all $i \leq k$. If such $x$ does not exists then the process stops.
The sequence $y_{1}, \ldots, y_{q}$ is computed in a similar way.
Next, $\mathcal{M}$ constructs a table $U$ of size $m \times n$. For every $i$ and $j$, the value of $U_{i, j}$ is defined as follows. If $i>p$ or $j>q$, then let $U_{i, j}=$ Reject. Otherwise, let $\tau_{s}$ be the initial segment of the input text $T$ consisting of the first $s$ strings in the text $T$. Check if the following two conditions are satisfied:

1) for every $x, x^{\prime} \leq_{l l e x} y_{j}$, if $x \equiv_{M, \alpha, s} x^{\prime}$, then $x \in \operatorname{content}\left(\tau_{s}\right)$ if and only if $x^{\prime} \in$ content $\left(\tau_{s}\right)$,
2) for every $k \leq i$ and every $y$, if $y \in \operatorname{content}\left(\tau_{s}\right)$ and $y \equiv_{M, \alpha, s} x_{k}$, then $x_{k} \in \operatorname{content}\left(\tau_{s}\right)$. If yes, then let $U_{i, j}=\left\{k: k \leq i\right.$ and $\left.x_{k} \in \operatorname{content}\left(\tau_{s}\right)\right\}$. Otherwise, let $U_{i, j}=$ Reject. After $U$ is constructed, $\mathcal{M}$ outputs an automaton $A$ associated with $U$ as described above. As the number of different possible $U$ is finite, the number of distinct corresponding automata output by $\mathcal{M}$ is finite.

Recall that $\mathcal{M}(\alpha, T, s)$ is the automaton output by learner $\mathcal{M}$ at step $s$ when processing the index $\alpha$ and the text $T$. To prove that the algorithm is correct we need to show that for every $\alpha \in I$ and every text $T$ such that content $(T) \in\left\{L_{\beta}\right\}_{\beta \in I}$,
a) if content $(T)=L_{\alpha}$ then for almost all $s, \mathcal{M}(\alpha, T, s)$ accepts $\alpha$,
b) if $\operatorname{content}(T) \neq L_{\alpha}$ then for almost all $s, \mathcal{M}(\alpha, T, s)$ rejects $\alpha$.

Recall that $m(\alpha)$ and $n(\alpha)$ are the numbers of the equivalence classes of $\equiv_{M, \alpha}$ and $\equiv_{N, \alpha}$, respectively. Note that there is a step $s_{0}$ after which the values $x_{1}<_{l l e x} \cdots<_{l l e x} x_{m(\alpha)}$ and $y_{1}<_{l l e x} \cdots<_{l l e x} y_{n(\alpha)}$ computed by $\mathcal{M}$ will always be equal to the $\leq_{l l e x}$ least representatives of the equivalence classes of $\equiv_{M, \alpha}$ and $\equiv_{N, \alpha}$, respectively.

Suppose that content $(T)=L_{\alpha}$. Hence, there is $s_{1} \geq s_{0}$ such that for every $s \geq s_{1}$ the following conditions are satisfied:

1) for every $k \leq m(\alpha), x_{k} \in \operatorname{content}\left(\tau_{s}\right)$ if and only if $x_{k} \in \operatorname{content}(T)$,
2) for every $x, x^{\prime} \leq_{l l e x} y_{n(\alpha)}$, if $x \equiv_{M, \alpha, s} x^{\prime}$, then $x \in \operatorname{content}\left(\tau_{s}\right)$ if and only if $x^{\prime} \in$ content $\left(\tau_{s}\right)$,
3) for every $k \leq m(\alpha)$ and every $y$, if $y \in \operatorname{content}\left(\tau_{s}\right)$ and $y \equiv_{M, \alpha, s} x_{k}$, then $x_{k} \in$ content $\left(\tau_{s}\right)$.
The last two conditions are satisfied since content $(T)=L_{\alpha}$ is the union of finitely many $\equiv_{M, \alpha}$ equivalence classes. Therefore, on every step $s \geq s_{1}$, the learner $\mathcal{M}$ constructs a table $U$ such that $U_{m(\alpha), n(\alpha)}=\left\{k: k \leq m(\alpha)\right.$ and $\left.x_{k} \in \operatorname{content}(T)\right\}$. By our construction of the automaton $A$ associated with $U, A$ accepts $\alpha$ if $L_{\alpha}=\left\{y: y \equiv_{M, \alpha} x_{k}\right.$ for some $\left.x_{k} \in \operatorname{content}(T)\right\}$. But since content $(T)=L_{\alpha}$, this condition is satisfied.

Now suppose that content $(T) \neq L_{\alpha}$. Note that for every $s \geq s_{0}, y_{n(\alpha)}$ computed by $\mathcal{M}$ at step $s$ has the property that $D_{\alpha}=\left\{x \in L_{\alpha}: x \leq_{l l e x} y_{n(\alpha)}\right\}$ is a tell-tale set for $L_{\alpha}$. This follows from the definition of the automaton $N$ and the fact that $y_{n(\alpha)}$ is the $\leq_{l l e x}$ largest among the representatives of the $\equiv_{N, \alpha}$ equivalence classes.

First, consider the case when $D_{\alpha} \nsubseteq$ content $(T)$, that is, there is $x \in L_{\alpha}, x \leq_{l l e x} y_{n(\alpha)}$ but $x \notin \operatorname{content}(T)$. Let $s_{1} \geq s_{0}$ be such that $x \equiv_{M, \alpha, s_{1}} x_{k}$ for some $k \leq m(\alpha)$. Note that $x_{k} \leq_{l l e x} x$ since $x_{k}$ is the minimal representative in its equivalence class. If for some $s_{2} \geq s_{1}, x_{k} \in \operatorname{content}\left(\tau_{s_{2}}\right)$, then from this step on $U_{m(\alpha), n(\alpha)}$ will be equal to Reject because of the Condition 1) in the definition of $U_{i, j}$. Hence $\mathcal{M}(\alpha, T, s)$ will reject $\alpha$ for all $s \geq s_{2}$. If $x_{k} \notin \operatorname{content}(T)$, then for all $s \geq s_{1}, \mathcal{M}(\alpha, T, s)$ will reject $\alpha$ either due to the fact that $U_{m(\alpha), n(\alpha)}=$ Reject at step $s$, or because $k \notin U_{m(\alpha), n(\alpha)}$ while it should be in $U_{m(\alpha), n(\alpha)}$ since both $x$ and $x_{k}$ are in $L_{\alpha}$.

Now suppose that $D_{\alpha} \subseteq \operatorname{content}(T)$. Since $D_{\alpha}$ is a tell-tale set for $L_{\alpha}$ and content $(T) \neq L_{\alpha}$, there is $x \in \operatorname{content}(T) \backslash L_{\alpha}$. Let $s_{1} \geq s_{0}$ be such that $x \in \operatorname{content}\left(\tau_{s_{1}}\right)$ and $x \equiv_{M, \alpha, s_{1}} x_{k}$ for some $k \leq m(\alpha)$. If $x_{k} \notin \operatorname{content}(T)$ then for every $s \geq s_{1}, U_{m(\alpha), n(\alpha)}=$ Reject and $\mathcal{M}(\alpha, T, s)$ will reject $\alpha$. If there is $s_{2} \geq s_{1}$ such that $x_{k} \in \operatorname{content}\left(\tau_{s_{2}}\right)$, then for every $s \geq s_{2}$ either $U_{m(\alpha), n(\alpha)}=$ Reject or $k \in U_{m(\alpha), n(\alpha)}$. In both cases $\mathcal{M}(\alpha, T, s)$ will reject $\alpha$ since $x_{k} \notin L_{\alpha}$.

Definition 3.2.1) Let $\alpha \in\{0,1, \ldots, k\}^{\omega}$ and $\beta \in\{1, \ldots, k\}^{\omega}$. The function $f_{\alpha, \beta}$ is defined as follows:

$$
f_{\alpha, \beta}(n)= \begin{cases}\alpha(m) & \text { if } m=\min \{x \geq n: \alpha(x) \neq 0\} \\ \lim \sup _{x \rightarrow \infty} \beta(x) & \text { if such } m \text { does not exist. }\end{cases}
$$

Let $L_{\alpha, \beta}$ be the set of all nonempty finite prefixes of $f_{\alpha, \beta}$, that is,

$$
L_{\alpha, \beta}=\left\{f_{\alpha, \beta}(0) \ldots f_{\alpha, \beta}(n): n \in \omega\right\} .
$$

2) Define the class $\mathcal{L}^{k}$ together with its indexing as follows. Let the index set be

$$
J_{k}=\left\{(\alpha, \beta): \alpha \in\{0,1, \ldots, k\}^{\omega}, \beta \in\{1,2, \ldots, k\}^{\omega}\right\}
$$

and let

$$
\mathcal{L}^{k}=\left\{L_{\alpha, \beta}\right\}_{(\alpha, \beta) \in J_{k}} .
$$

Note that the class $\mathcal{L}^{k}$ is uncountable and automatic.

Theorem 3.3. For every $k \geq 2$, the class $\mathcal{L}^{k}=\left\{L_{\alpha, \beta}\right\}_{(\alpha, \beta) \in J_{k}}$ is in $\mathbf{F E x}_{k} \backslash \mathbf{F E x}_{k-1}$.
Proof. We first show that $\mathcal{L}^{k}$ is $\mathbf{F E x}{ }_{k}$-learnable. Let $A_{0}, A_{1}, \ldots, A_{k}$ be automata such that $A_{0}$ rejects all $\omega$-strings, and for $i=1, \ldots, k$

$$
A_{i} \text { accepts }(\alpha, \beta) \Longleftrightarrow \limsup _{x \rightarrow \infty} \alpha(x) \neq 0 \text { or } \limsup _{x \rightarrow \infty} \beta(x)=i
$$

A learner $\mathcal{M}$ that $\mathbf{F E x}{ }_{k}$-learns $\mathcal{L}^{k}$ acts as follows. At every step $s, \mathcal{M}$ reads the first $s$ inputs from the input text. If all these inputs are equal to $\#$, then $\mathcal{M}$ outputs $A_{0}$. Otherwise, let $t_{s}$ be the longest string among them. Next, $\mathcal{M}$ checks if $t_{s}$ is consistent with $\alpha$, that is, if there is a $j$ with $1 \leq j \leq k$ such that for every $n<\left|t_{s}\right|$,

$$
t_{s}(n)= \begin{cases}\alpha(m) & \text { if } m=\min \left\{x: n \leq x<\left|t_{s}\right| \text { and } \alpha(x) \neq 0\right\} \\ j & \text { if such } m \text { does not exist. }\end{cases}
$$

If $t_{s}$ is inconsistent with $\alpha$, then $\mathcal{M}$ outputs only the automaton $A_{0}$ from step $s$ onward. Otherwise, in the end of step $s$ the learner $\mathcal{M}$ outputs $A_{i}$, where $i$ is the last symbol of $t_{s}$. Now it is not hard to verify that this algorithm is correct.

To show that $\mathcal{L}^{k}$ is not in $\mathbf{F E x}_{k-1}$, assume, for the sake of contradiction, that there is a learner $\mathcal{M}$ that can $\mathbf{F E x} x_{k-1}$-learn $\mathcal{L}^{k}$. First, we need the following two lemmas.
Lemma 3.4. There are finite strings $\alpha^{\prime}$, $\beta^{\prime}$ and $k-1$ automata $A_{1}, \ldots, A_{k-1}$ such that
a) $\alpha^{\prime} \in\{0,1, \ldots, k\}^{*}, \beta^{\prime} \in\{1, \ldots, k\}^{*}$ and $\left|\alpha^{\prime}\right|=\left|\beta^{\prime}\right|$,
b) for every $\omega$-string $\beta$ such that $\beta^{\prime} \subset \beta \in\{1, \ldots, k\}^{\omega}$, there is a text $T$ for $L_{\alpha^{\prime} 0^{\omega}, \beta}$ (which can be chosen to be the canonical text for $\left.L_{\alpha^{\prime} 0^{\omega}, \beta}\right)$ such that the learner $\mathcal{M}$ on index $\left(\alpha^{\prime} 0^{\omega}, \beta\right)$ and text $T$ oscillates only between $A_{1}, \ldots, A_{k-1}$ after it has seen ( $\alpha^{\prime}, \beta^{\prime}$ ).

Proof of Lemma 3.4. Suppose that there are no such $\alpha^{\prime}, \beta^{\prime}$ and $A_{1}, \ldots, A_{k-1}$. In other words, for any $\alpha^{\prime}, \beta^{\prime}$ for which property a) holds and any $k-1$ automata $A_{1}, \ldots, A_{k-1}$, there are an $\omega$-string $\beta$ with $\beta^{\prime} \subset \beta \in\{1, \ldots, k\}^{\omega}$ and an automaton $A \notin\left\{A_{1}, \ldots, A_{k-1}\right\}$ such that $\mathcal{M}$ outputs $A$ above ( $\alpha^{\prime}, \beta^{\prime}$ ) when processing the index $\left(\alpha^{\prime} 0^{\omega}, \beta\right)$ and the canonical text for $L_{\alpha^{\prime} 0^{\omega}, \beta}$, that is, $\mathcal{M}$ outputs $A$ at some step after the first step at which it has seen $\left(\alpha^{\prime}, \beta^{\prime}\right)$.

We now show that $\mathcal{L}^{k} \notin \mathbf{F E x}_{k-1}$ by constructing $\omega$-strings $\alpha, \beta$ and a text $T$ for $L_{\alpha, \beta}$ such that $\mathcal{M}$ oscillates between more than $k-1$ many automata when processing $(\alpha, \beta)$ and $T$. At each step $i$, we will construct finite strings $\alpha_{i}, \alpha_{i}^{\prime}, \beta_{i}, \beta_{i}^{\prime}$ and a finite text segment $\tau_{i}$ such that the following properties hold:

1) $\alpha_{i}, \alpha_{i}^{\prime} \in\{0,1, \ldots, k\}^{*}$ and $\beta_{i}, \beta_{i}^{\prime} \in\{1, \ldots, k\}^{*}$.
2) $\left|\alpha_{i}\right|=\left|\beta_{i}\right|$ and $\left|\alpha_{i}^{\prime}\right|=\left|\beta_{i}^{\prime}\right|$.
3) $\alpha_{i}^{\prime} \subseteq \alpha_{i} \subseteq \alpha_{i+1}^{\prime}, \beta_{i}^{\prime} \subseteq \beta_{i} \subseteq \beta_{i+1}^{\prime}$, and $\tau_{i} \subseteq \tau_{i+1}$.
4) $\alpha=\bigcup_{i \in \omega} \alpha_{i}, \beta=\bigcup_{i \in \omega} \beta_{i}$ and $T=\bigcup_{i \in \omega} \tau_{i}$.
5) For $i>0, \alpha_{i}$ does not end in 0 .
6) $\tau_{i}$ is a finite prefix of the canonical text for $L_{\alpha_{i} 0^{\omega}, \beta}$ that contains strings of length not greater than $\left|\alpha_{i}\right|$ (for some $\beta$, but since $\alpha_{i}$ does not end in 0 and since we only consider strings which are shorter than $\alpha_{i}$, this $\beta$ is irrelevant).
7) When the learner $\mathcal{M}$ processes the input ( $\alpha_{i}, \beta_{i}$ ) and the text segment $\tau_{i}$, it does not try to read beyond $\tau_{i}$ in the text before it reads beyond the prefix $\left(\alpha_{i}^{\prime}, \beta_{i}^{\prime}\right)$ of $\left(\alpha_{i}, \beta_{i}\right)$. At step 0 , let all $\alpha_{0}^{\prime}, \alpha_{0}, \beta_{0}^{\prime}, \beta_{0}$ and $\tau_{0}$ be equal to the empty string. At step $i+1$, let $A_{1}, \ldots, A_{k-1}$ be the last $k-1$ different automata output by $\mathcal{M}$ up to the first step at which it has seen $\left(\alpha_{i}^{\prime}, \beta_{i}^{\prime}\right)$ when processing $\left(\alpha_{i}, \beta_{i}\right)$ on text segment $\tau_{i}$ (if there are less then $k-1$ such automata, then consider the set of all these automata instead of $A_{1}, \ldots, A_{k-1}$ ).

By our assumption, there are an $\omega$-string $\beta$ with $\beta_{i} \subset \beta \in\{1, \ldots, k\}^{\omega}$ and an automaton $A \notin\left\{A_{1}, \ldots, A_{k-1}\right\}$ such that $\mathcal{M}$ outputs $A$ above $\left(\alpha_{i}, \beta_{i}\right)$ when processing $\left(\alpha_{i} 0^{\omega}, \beta\right)$ and the canonical text $T^{\prime}$ for $L_{\alpha_{i} 0^{\omega}, \beta}$. Due to property 6), $T^{\prime}$ extends $\tau_{i}$.

Now wait until the learner $\mathcal{M}$ outputs $A \notin\left\{A_{1}, \ldots, A_{k-1}\right\}$ on $\left(\alpha_{i} 0^{\omega}, \beta\right)$ and $T^{\prime}$ above $\left(\alpha_{i}, \beta_{i}\right)$. Let $\left(\alpha_{i+1}^{\prime}, \beta_{i+1}^{\prime}\right)$ and $\tau_{i+1}$ be the finite segments of the index and the text seen by that time. Here, if $\tau_{i+1}$ does not properly extend $\tau_{i}$, then we take $\tau_{i+1}$ to be the extension of $\tau_{i}$ by one more symbol; furthermore, if $\tau_{i+1}$ ends in a middle of a string from $T^{\prime}$, then we extend $\tau_{i+1}$ up to the beginning of the next string.

Let $t$ be the maximum of $\left|\alpha_{i+1}^{\prime}\right|+1$ and the length of the longest string from $\tau_{i+1}$. Let $\alpha_{i+1}=\alpha_{i+1}^{\prime} 0^{s} m$, where $m=\lim \sup _{x \rightarrow \infty} \beta(x)$ and $s$ is chosen in such a way that $\left|\alpha_{i+1}\right|=t$. Finally, let $\beta_{i+1}$ be the prefix of $\beta$ of length $t$. This concludes the description of step $i+1$.

Now, by the construction, $T$ is a text for $L_{\alpha, \beta}$ (in fact, the canonical one), and $\mathcal{M}$ oscillates between more then $k-1$ many automata when processing $(\alpha, \beta)$ and $T$.

This completes the proof of Lemma 3.4.
Lemma 3.5. Suppose that there is $l$ such that $1<l<k$, and there are $l$ many automata $A_{1}, \ldots, A_{l}$ together with finite strings $\alpha^{\prime}, \beta^{\prime}$ with the following properties:
a) $\alpha^{\prime} \in\{0,1, \ldots, k\}^{*}, \beta^{\prime} \in\{1, \ldots, k\}^{*}$ and $\left|\alpha^{\prime}\right|=\left|\beta^{\prime}\right|$,
b) for every $\omega$-string $\beta \supset \beta^{\prime}$ such that $1 \leq \beta(x) \leq l+1$ for all $x \geq\left|\beta^{\prime}\right|$, the learner $\mathcal{M}$ on index $\left(\alpha^{\prime} 0^{\omega}, \beta\right)$ and the canonical text for $L_{\alpha^{\prime} 0^{\omega}, \beta}$ oscillates only between $A_{1}, \ldots, A_{l}$ after it has seen $\left(\alpha^{\prime}, \beta^{\prime}\right)$.

Then there are $l-1$ many automata $\left\{A_{1}^{\prime}, \ldots, A_{l-1}^{\prime}\right\} \subset\left\{A_{1}, \ldots, A_{l}\right\}$ and finite strings $\alpha^{\prime \prime}$, $\beta^{\prime \prime}$ such that

1) $\alpha^{\prime \prime} \in \alpha^{\prime}\{0\}^{*}, \beta^{\prime \prime} \in \beta^{\prime}\{1, \ldots, l+1\}^{*}$ and $\left|\alpha^{\prime \prime}\right|=\left|\beta^{\prime \prime}\right|$,
2) for every $\omega$-string $\beta \supset \beta^{\prime \prime}$ such that $1 \leq \beta(x) \leq l$ for all $x \geq\left|\beta^{\prime \prime}\right|$, the learner $\mathcal{M}$ on index $\left(\alpha^{\prime \prime} 0^{\omega}, \beta\right)$ and the canonical text for $L_{\alpha^{\prime \prime} 0^{\omega}, \beta}$ oscillates only between $A_{1}^{\prime}, \ldots, A_{l-1}^{\prime}$ after it has seen $\left(\alpha^{\prime \prime}, \beta^{\prime \prime}\right)$.

Proof of Lemma 3.5. Assume that there are no such $\alpha^{\prime \prime}, \beta^{\prime \prime}$ and $A_{1}^{\prime}, \ldots, A_{l-1}^{\prime}$. Thus, for any $A \in\left\{A_{1}, \ldots, A_{l}\right\}$ and any $\alpha^{\prime \prime}, \beta^{\prime \prime}$ for which property 1) holds, there is an $\omega$-string $\beta \in \beta^{\prime \prime}\{1, \ldots, l\}^{\omega}$ such that the learner $\mathcal{M}$ outputs $A$ on $\left(\alpha^{\prime \prime} 0^{\omega}, \beta\right)$ and the canonical text for $L_{\alpha^{\prime \prime} 0^{\omega}, \beta}$ above ( $\alpha^{\prime \prime}, \beta^{\prime \prime}$ ).

For $n$ with $1 \leq n \leq l$, let $T_{n}$ be the canonical text for $L_{\alpha^{\prime} 0^{\omega}, n^{\omega}}$. We will construct an $\omega$-string $\beta \in \beta^{\prime}\{1, \ldots, l+1\}^{\omega}$ with $\limsup _{x \rightarrow \infty} \beta(x)=l+1$. Moreover, for every $A \in$ $\left\{A_{1}, \ldots, A_{l}\right\}$, there will be $n \in\{1, \ldots, l\}$ such that $\mathcal{M}$ outputs $A$ infinitely often on index $\left(\alpha^{\prime} 0^{\omega}, \beta\right)$ and text $T_{n}$. At each step $i$ we will construct a finite string $\beta_{i} \in \beta^{\prime}\{1, \ldots, l+1\}^{*}$ such that $\beta_{i} \subseteq \beta_{i+1}$ and $\beta=\bigcup_{i} \beta_{i}$.

At step 0 , let $\beta_{0}=\beta^{\prime}$. At step $i+1$, let $m \in\{1, \ldots, l\}$ be such that $m \equiv i+1(\bmod l)$. By our assumption, there exists an $\omega$-string $\beta \in \beta_{i}\{1, \ldots, l\}^{\omega}$, and $\mathcal{M}$ outputs $A_{m}$ on $\left(\alpha^{\prime} 0^{\omega}, \beta\right)$ and $T_{n}$ above $\left(\alpha^{\prime} 0^{s}, \beta_{i}\right)$, where $n=\lim \sup _{x \rightarrow \infty} \beta(x)$ and $s=\left|\beta_{i}\right|-\left|\alpha^{\prime}\right|$. Now let $\beta_{i}^{\prime} \supseteq \beta_{i}$ be the finite prefix of $\beta$ seen by $\mathcal{M}$ when it outputs $A_{m}$ for the first time above ( $\alpha^{\prime} 0^{s}, \beta_{i}$ ) on text $T_{n}$, and let $\beta_{i+1}$ be equal to $\beta_{i}^{\prime}(l+1)$, that is, $\beta_{i}^{\prime}$ followed by number $l+1$. This concludes step $i+1$.

By the construction, $\lim \sup _{x \rightarrow \infty} \beta(x)=l+1$ and for every $m=1, \ldots, l$ and every $r \in \omega$, there is $n \in\{1, \ldots, l\}$ such that $\mathcal{M}$ outputs $A_{m}$ after reading $\left(\alpha^{\prime} 0^{s}, \beta_{r \cdot l+m}\right)$ on text $T_{n}$, where $s=\left|\beta_{r \cdot l+m}\right|-\left|\alpha^{\prime}\right|$. Therefore, for every $A \in\left\{A_{1}, \ldots, A_{l}\right\}$, there is $n \in\{1, \ldots, l\}$ such that $\mathcal{M}$ outputs $A$ infinitely often on $\left(\alpha^{\prime} 0^{\omega}, \beta\right)$ and $T_{n}$.

Since $\lim \sup _{x \rightarrow \infty} \beta(x)=l+1$, each $T_{n}$ is different from $L_{\alpha^{\prime} 0^{\omega}, \beta}$. So, every $A \in\left\{A_{1}, \ldots, A_{l}\right\}$ must reject $\left(\alpha^{\prime} 0^{\omega}, \beta\right)$. On the other hand, since $\beta \in \beta^{\prime}\{1, \ldots, l+1\}^{\omega}$, the learner $\mathcal{M}$ on index $\left(\alpha^{\prime} 0^{\omega}, \beta\right)$ and the canonical text for $L_{\alpha^{\prime} 0^{\omega}, \beta}$ oscillates only between $A_{1}, \ldots, A_{l}$ after it has seen $\left(\alpha^{\prime}, \beta^{\prime}\right)$. So, there is $A \in\left\{A_{1}, \ldots, A_{l}\right\}$ which is output by $\mathcal{M}$ infinitely often, and this $A$ must accept $\left(\alpha^{\prime} 0^{\omega}, \beta\right)$. But we just showed that every such $A$ must reject $\left(\alpha^{\prime} 0^{\omega}, \beta\right)$. This contradiction proves the lemma.

This completes the proof of Lemma 3.5.
By Lemma 3.4, the assumption of Lemma 3.5 holds for $l=k-1$. Now, applying Lemma 3.5 inductively for $l$ from $k-1$ down to 2 , we eventually obtain that there are finite strings $\alpha^{\prime}$, $\beta^{\prime}$ and an automaton $A$ such that

1) $\alpha^{\prime} \in\{0,1, \ldots, k\}^{*}, \beta^{\prime} \in\{1, \ldots, k\}^{*}$ and $\left|\alpha^{\prime}\right|=\left|\beta^{\prime}\right|$,
2) for every $\omega$-string $\beta \supset \beta^{\prime}$ such that $\beta(x) \in\{1,2\}$ for all $x \geq\left|\beta^{\prime}\right|$, the learner $\mathcal{M}$ on index $\left(\alpha^{\prime} 0^{\omega}, \beta\right)$ and the canonical text for $L_{\alpha^{\prime} 0^{\omega}, \beta}$ outputs only $A$ above $\left(\alpha^{\prime}, \beta^{\prime}\right)$.

For $n \in\{1,2\}$, let $T_{n}$ be the canonical text for $L_{\alpha^{\prime} 0^{\omega}, n^{\omega}}$. We now construct an $\omega$-string $\beta \in \beta^{\prime}\{1,2\}^{\omega}$ with $\lim \sup _{x \rightarrow \infty} \beta(x)=2$ such that $\mathcal{M}$ outputs only $A$ on $\left(\alpha^{\prime} 0^{\omega}, \beta\right)$ and $T_{1}$ above $\left(\alpha^{\prime}, \beta^{\prime}\right)$. Again, for every $i$, we will construct $\beta_{i} \in \beta^{\prime}\{1,2\}^{*}$ such that $\beta_{i} \subseteq \beta_{i+1}$ and $\beta=\bigcup_{i} \beta_{i}$.

Let $\beta_{0}=\beta^{\prime}$. Suppose we have constructed $\beta_{i}$. By our assumption, the learner $\mathcal{M}$ on $\left(\alpha^{\prime} 0^{\omega}, \beta_{i} 1^{\omega}\right)$ and $T_{1}$ outputs only $A$ above $\left(\alpha^{\prime}, \beta^{\prime}\right)$. Now wait until the first step when $\mathcal{M}$ outputs $A$ above $\left(\alpha^{\prime} 0^{s}, \beta_{i}\right)$, where $s=\left|\beta_{i}\right|-\left|\alpha^{\prime}\right|$. Let $\beta_{i}^{\prime} \supseteq \beta_{i}$ be the finite prefix of $\beta_{i} 1^{\omega}$ seen by $\mathcal{M}$ by that time, and let $\beta_{i+1}=\beta_{i}^{\prime} 2$.

Since $\lim \sup _{x \rightarrow \infty} \beta(x)=2$ and since $\mathcal{M}$ outputs only $A$ on $\left(\alpha^{\prime} 0^{\omega}, \beta\right)$ and $T_{1}$ above $\left(\alpha^{\prime}, \beta^{\prime}\right)$, $A$ must reject $\left(\alpha^{\prime} 0^{\omega}, \beta\right)$. On the other hand, $\mathcal{M}$ on $\left(\alpha^{\prime} 0^{\omega}, \beta\right)$ and $T_{2}$ outputs only $A$ above $\left(\alpha^{\prime}, \beta^{\prime}\right)$. Therefore, $A$ must accept $\left(\alpha^{\prime} 0^{\omega}, \beta\right)$. This contradiction proves the theorem.

Remark 3.6. The last result can be strengthened in the following sense: for every $k \geq 1$ there is an indexing $\left\{L_{\beta}\right\}_{\beta \in I}$ of the class $\mathcal{L}=\left\{\left\{\alpha_{0} \alpha_{1} \alpha_{2} \ldots \alpha_{n-1}: n \in \omega\right\}: \alpha \in\{1,2\}^{\omega}\right\}$ such that $\left\{L_{\beta}\right\}_{\beta \in I}$ is $\mathbf{F E x}_{k+1}$-learnable but not $\mathbf{F E x}_{k}$-learnable. That is, the class can be kept fixed and only the indexing has to be adjusted. In order to keep the proof above more readable, this adjustment was not implemented there.

## 4 Explanatory Learning

The main result of this section is that for every class that satisfies Angluin's tell-tale condition, there is an indexing in which the class is explanatorily learnable. A learner which we construct will, in general, have a mind change sequence which is a subsequence of Reject-Accept-Reject. That is, at first, the learner may think that the index is wrong and reject it. Then it may change its mind and start to think that the index is correct and accept it. In the end, the learner may change its mind again, and in this case it will keep rejecting the index forever. The mind changes mentioned above are the worst case, and in some situations, such mind changes may not happen. In the second part of this section we will consider such patterns of mind changes in more detail and characterize the classes that can be learnt that way.

Theorem 4.1. If a class $\mathcal{L}=\left\{L_{\alpha}\right\}_{\alpha \in I}$ satisfies Angluin's tell-tale condition, then there is an indexing for $\mathcal{L}$ such that $\mathcal{L}$ with this indexing is Ex-learnable.

Proof. Let $M$ be a deterministic automaton recognizing $\left\{(x, \alpha): x \in L_{\alpha}\right\}$, and $Q_{M}$ be its set of states. The set $J$ of new indices for $\mathcal{L}$ will consist of convolutions $\otimes(\alpha, \beta, \gamma)$, where $\alpha \in I$, $\beta \in\{0,1\}^{\omega}$ determines a tell-tale set for $L_{\alpha}$, and $\gamma \in\left\{\mathcal{P}\left(Q_{M}\right)\right\}^{\omega}$ keeps track of states of $M$ when it reads $\otimes(x, \alpha)$ for some finite strings $x \in L_{\alpha}$. To simplify the notations we will write $(\alpha, \beta, \gamma)$ instead of $\otimes(\alpha, \beta, \gamma)$. Formally, $J$ is defined as follows:

$$
\begin{aligned}
(\alpha, \beta, \gamma) \in J \Longleftrightarrow & \alpha \in I, \beta=0^{n} 1^{\omega} \text { for the minimal } n \text { such that } \\
& \left\{x \in L_{\alpha}:|x|<n\right\} \text { is a tell-tale set for } L_{\alpha}, \text { and for every } k \\
& \gamma(k)=\left\{q \in Q_{M}: \exists x \in L_{\alpha}\left(|x| \leq k \text { and } \operatorname{St}_{M}(\otimes(x, \alpha), k)=q\right)\right\}
\end{aligned}
$$

We want to show that $J$ is automatic. Again, it is enough to show that it is first-order definable from other automatic relations. We can define $\beta$ as the lexicographically largest $\beta^{\prime}$ that satisfies the formula:

$$
\beta^{\prime} \in 0^{*} 1^{\omega} \& \forall \sigma \in 0^{*}\left(\left(\sigma \subseteq \beta^{\prime} \& \sigma 0 \nsubseteq \beta^{\prime}\right) \rightarrow\left\{x \in L_{\alpha}:|x|<|\sigma|\right\} \text { is a tell-tale set for } L_{\alpha}\right) .
$$

The first-order definition for a tell-tale set is given in the beginning of the proof of Theorem 3.1. All other relations in this definition are clearly automatic.

The definition for $\gamma$ can be written as

$$
\forall \sigma \in 0^{*} \bigwedge_{q \in Q_{M}}\left(q \in \gamma(|\sigma|) \leftrightarrow \exists x \in L_{\alpha}\left(|x| \leq|\sigma| \& S t_{M}(\otimes(x, \alpha),|\sigma|)=q\right)\right)
$$

For every $q \in Q_{M}$, there are automata $A_{q}$ and $B_{q}$ that recognize the relations

$$
\left.\left\{(\sigma, \gamma): \sigma \in 0^{*} \& q \in \gamma(|\sigma|)\right\} \quad \text { and } \quad\left\{(\sigma, x, \alpha): \sigma \in 0^{*} \& S t_{M}(\otimes(x, \alpha),|\sigma|)=q\right)\right\}
$$

Therefore, $J$ is first-order definable from automatic relations, and hence itself is automatic.
We now show that for every finite string $x$,

$$
x \in L_{\alpha} \Longleftrightarrow S t_{M}(\otimes(x, \alpha),|x|) \in \gamma(|x|),
$$

provided that $\gamma$ is correctly defined from $\alpha$ as in the definition of $J$. Indeed, if $x \in L_{\alpha}$, then $S t_{M}(\otimes(x, \alpha),|x|) \in \gamma(|x|)$ by the definition of $\gamma$. On the other hand, if $S t_{M}(\otimes(x, \alpha),|x|) \in$ $\gamma(|x|)$, then, again by the definition of $\gamma$, there is $y \in L_{\alpha}$ with $|y| \leq|x|$ such that

$$
S t_{M}(\otimes(y, \alpha),|x|)=S t_{M}(\otimes(x, \alpha),|x|)
$$

Therefore, after $|x|$ many steps the run of $M$ on $\otimes(x, \alpha)$ coincides with the run on $\otimes(y, \alpha)$. Hence $M$ accepts $\otimes(x, \alpha)$, and $x$ is in $L_{\alpha}$.

We define a new indexing $\left\{H_{\alpha, \beta, \gamma}\right\}_{(\alpha, \beta, \gamma) \in J}$ for the class $\mathcal{L}$ as follows

$$
H_{\alpha, \beta, \gamma}=L_{\alpha} .
$$

Clearly, this indexing is automatic since

$$
x \in H_{\alpha, \beta, \gamma} \Longleftrightarrow x \in L_{\alpha} \text { and }(\alpha, \beta, \gamma) \in J
$$

Now we describe a learner $\mathcal{M}$ that can Ex-learn the class $\mathcal{L}$ in the new indexing. Let $A$ be an automaton that recognizes the set $J$, and let $Z$ be an automaton that rejects all $\omega$-strings. The learner $\mathcal{M}$ will output only automata $A$ and $Z$ in a sequence $Z-A-Z$ (or a subsequence of this). In other words, $\mathcal{M}$ can start outputting automaton $Z$, then change its mind to $A$ and then again change its mind to $Z$, after which it will be outputting $Z$ forever.

When an index $(\alpha, \beta, \gamma)$ is given to the learner $\mathcal{M}$, it always assumes that $\beta$ and $\gamma$ are correctly defined from $\alpha$. Otherwise, it does not matter which automaton $\mathcal{M}$ will output in the limit, since both $A$ and $Z$ will reject the index $(\alpha, \beta, \gamma)$.

At every step $s, \mathcal{M}$ reads the first $s$ inputs $x_{1}, \ldots, x_{s}$ from the input text. Then $\mathcal{M}$ outputs $A$ if the following conditions hold:

- There exists $n \leq s$ such that $0^{n} 1 \subseteq \beta$.
- For every $i$ with $x_{i} \neq \#, x_{i}$ belongs to $L_{\alpha}$ according to $\gamma$, i.e., $S t_{M}\left(\otimes\left(x_{i}, \alpha\right),\left|x_{i}\right|\right) \in$ $\gamma\left(\left|x_{i}\right|\right)$.
- For every $x$ with $|x|<n$, if $x$ belongs to $L_{\alpha}$ according to $\gamma$, then $x \in\left\{x_{1}, \ldots, x_{s}\right\}$.

Otherwise, $\mathcal{M}$ outputs $Z$. This concludes the step $s$.
Note that $\mathcal{M}$ makes a change from $Z$ to $A$ or from $A$ to $Z$ at most once. Thus it always converges to one of these automata. If the index $(\alpha, \beta, \gamma)$ is not in $J$, then $\mathcal{M}$ always rejects it. If $(\alpha, \beta, \gamma) \in J$, then for every $x$, we have that $x \in L_{\alpha}$ according to $\gamma$ if and only if $x$ is indeed in $L_{\alpha}$. Moreover, the set

$$
D_{n}=\left\{x:|x|<n \text { and } x \in L_{\alpha} \text { according to } \gamma\right\}
$$

is a tell-tale set for $L_{\alpha}$, where $n$ is such that $\beta=0^{n} 1^{\omega}$.
Let $T$ be the input text. If content $(T)=H_{\alpha, \beta, \gamma}$, then there is a step $s \geq n$ such that $D_{n}$ is contained in $\left\{x_{1}, \ldots, x_{s}\right\}$. Therefore, $\mathcal{M}$ will output only $A$ from step $s$ onward. If $\operatorname{content}(T) \neq H_{\alpha, \beta, \gamma}$, then $D_{n} \nsubseteq \operatorname{content}(T)$ or content $(T) \nsubseteq H_{\alpha, \beta, \gamma}$. In the first case, $\mathcal{M}$ will output $Z$ on every step. In the second case, there is a step $s$ and an $x_{i} \in\left\{x_{1}, \ldots, x_{s}\right\}$ such that $x_{i} \neq \#$ and $x_{i}$ is not in $L_{\alpha}$ according to $\gamma$. Therefore, $\mathcal{M}$ will output $Z$ from step $s$ onward. This proves the correctness of the algorithm.

In the previous theorem we showed that a class $\mathcal{L}$ can be $\mathbf{E x}$-learnt in a suitable indexing with the Reject-Accept-Reject sequence of mind changes (or a subsequence thereof) if and only if it satisfies Angluin's tell-tale condition. In the rest of this section we will characterize the classes that are Ex-learnable with the sequences of mind changes as Accept-Reject, RejectAccept and Accept-Reject-Accept (or a subsequence thereof). For the ease of notation, we will drop the phrase "or a subsequence thereof" in the following.
Theorem 4.2. For every automatic class $\mathcal{L}$, the following are equivalent:

1) $\mathcal{L}$ can be Ex-learnt with the Accept-Reject sequence of mind changes in a suitable indexing.
2) $\mathcal{L}$ is an inclusion free class, that is, $\forall L, L^{\prime} \in \mathcal{L}\left(L^{\prime}\right.$ is not a proper subset of $\left.L\right)$.

Proof. Suppose that there is a learner $\mathcal{M}$ that Ex-learns $\mathcal{L}$ with the sequence of mind changes as Accept-Reject in the indexing $\left\{L_{\alpha}\right\}_{\alpha \in I}$, and suppose that there are different sets $L_{\alpha}$ and $L_{\beta}$ such that $L_{\alpha} \subset L_{\beta}$. Run the learner $\mathcal{M}$ on the index $\beta$ and some text for $L_{\alpha}$. Since $L_{\alpha} \neq L_{\beta}$, there is a step $s$ at which $\mathcal{M}$ changes its mind to Reject. Let $\tau_{s}$ be the finite segment of the text seen by $\mathcal{M}$ at step $s$. Since $L_{\alpha} \subset L_{\beta}$, we can extend $\tau_{s}$ to a text $T$ for $L_{\beta}$. Then $\mathcal{M}$ will reject $\beta$ on text $T$, which is impossible. Therefore, $\mathcal{L}$ is inclusion free.

Now let $\mathcal{L}=\left\{L_{\alpha}\right\}_{\alpha \in I}$ be an inclusion free class, and let $M$ be a deterministic automaton recognizing $\left\{(x, \alpha): x \in L_{\alpha}\right\}$. Consider a new set of indices $J$ defined as

$$
\begin{aligned}
(\alpha, \gamma) \in J \Longleftrightarrow & \alpha \in I \text { and for every } k, \gamma(k)= \\
& \left\{q \in Q_{M}: \exists x \in L_{\alpha}\left(|x| \leq k \text { and } S t_{M}(\otimes(x, \alpha), k)=q\right)\right\}
\end{aligned}
$$

Define a new automatic indexing $\left\{H_{\alpha, \gamma}\right\}_{(\alpha, \gamma) \in J}$ for the class $\mathcal{L}$ as

$$
H_{\alpha, \gamma}=L_{\alpha} .
$$

Let $A$ be an automaton that recognizes the set $J$, and let $Z$ be an automaton that rejects all $\omega$-strings. The learner $\mathcal{M}$ that Ex-learns $\mathcal{L}$ in this new indexing works as follows. At every step $s, \mathcal{M}$ reads the first $s$ inputs $x_{1}, \ldots, x_{s}$ from the input text. If every $x_{i}$ which is not equal to the pause symbol \# belongs to $H_{\alpha, \gamma}$ according to $\gamma$, i.e., if $S t_{M}\left(\otimes\left(x_{i}, \alpha\right),\left|x_{i}\right|\right) \in \gamma\left(\left|x_{i}\right|\right)$, then $\mathcal{M}$ outputs $A$. Otherwise, $\mathcal{M}$ outputs $Z$.

One can verify that $\mathcal{M}$ Ex-learns $\left\{H_{\alpha, \gamma}\right\}_{(\alpha, \gamma) \in J}$ with the Accept-Reject sequence of mind changes.

Theorem 4.3. For every automatic class $\mathcal{L}$, the following are equivalent:

1) $\mathcal{L}$ can be Ex-learnt with the Reject-Accept sequence of mind changes in a suitable indexing.
2) For every $L \in \mathcal{L}$ there is a finite $D_{L} \subseteq L$ such that for every $L^{\prime} \in \mathcal{L}$, if $D_{L} \subseteq L^{\prime}$ then $L^{\prime}=L$.

Proof. Suppose that there is a learner $\mathcal{M}$ that Ex-learns $\mathcal{L}$ with the sequence of mind changes as Reject-Accept in the indexing $\left\{L_{\alpha}\right\}_{\alpha \in I}$. Run $\mathcal{M}$ on an index $\alpha$ and any text for $L_{\alpha}$. There must be a step $s$ at which $\mathcal{M}$ changes its mind to Accept. Let $\tau_{s}$ be the finite segment of the input text seen by $\mathcal{M}$ at step $s$, and let $D_{\alpha}=\operatorname{content}\left(\tau_{s}\right)$. Suppose that there is $L_{\beta} \neq L_{\alpha}$ such that $D_{\alpha} \subseteq L_{\beta}$. Consider a text $T$ for $L_{\beta}$ that extends $\tau_{s}$. If we run $\mathcal{M}$ on index $\alpha$ and
text $T$, then at step $s$ the learner will change its mind to Accept, and after that it will be accepting $\alpha$ forever. On the other hand, $\mathcal{M}$ must eventually reject $\alpha$ since $L_{\alpha} \neq \operatorname{content}(T)$. Therefore, $\mathcal{L}$ satisfies the condition 2) of the theorem.

Suppose that the class $\mathcal{L}=\left\{L_{\alpha}\right\}_{\alpha \in I}$ satisfies condition 2) of the theorem. Let $M$ be a deterministic automaton that recognizes $\left\{(x, \alpha): x \in L_{\alpha}\right\}$. The set $J$ of new indices is defined as follows:

$$
\begin{aligned}
(\alpha, \beta, \gamma) \in J \Longleftrightarrow & \alpha \in I, \beta=0^{n} 1^{\omega} \text { for the minimal } n \text { such that for every } \alpha^{\prime} \in I \\
& \left(\left\{x \in L_{\alpha}:|x|<n\right\} \subseteq L_{\alpha^{\prime}} \Rightarrow L_{\alpha^{\prime}}=L_{\alpha}\right), \text { and for every } k \\
& \gamma(k)=\left\{q \in Q_{M}: \exists x \in L_{\alpha}\left(|x| \leq k \text { and } \operatorname{St}_{M}(\otimes(x, \alpha), k)=q\right)\right\}
\end{aligned}
$$

Using a similar argument as in the proof of Theorem 4.1, one can show that $J$ is automatic. Define a new automatic indexing $\left\{H_{\alpha, \beta, \gamma}\right\}_{(\alpha, \beta, \gamma) \in J}$ for the class $\mathcal{L}$ as follows

$$
H_{\alpha, \beta, \gamma}=L_{\alpha}
$$

Let $A$ be an automaton that recognizes the set $J$, and let $Z$ be an automaton that rejects all $\omega$-strings. The learner $\mathcal{M}$ that Ex-learns $\mathcal{L}$ in this new indexing works as follows. At every step $s, \mathcal{M}$ reads the first $s$ inputs $x_{1}, \ldots, x_{s}$ from the input text. Then $\mathcal{M}$ outputs $A$ if the following conditions hold:

- There exists $n \leq s$ such that $0^{n} 1 \subseteq \beta$.
- If $0^{n} 1 \subseteq \beta$, then for every $x$ with $|x|<n$, if $x$ belongs to $L_{\alpha}$ according to $\gamma$, i.e., $S t_{M}(\otimes(x, \alpha),|x|) \in \gamma(|x|)$, then $x \in\left\{x_{1}, \ldots, x_{s}\right\}$.
Otherwise, $\mathcal{M}$ outputs $Z$.
From this description of $\mathcal{M}$ one can see that it Ex-learns $\left\{H_{\alpha, \beta, \gamma}\right\}_{(\alpha, \beta, \gamma) \in J}$ with the RejectAccept sequence of mind changes.

Theorem 4.4. For every automatic class $\mathcal{L}$, the following are equivalent:

1) $\mathcal{L}$ can be Ex-learnt with the Accept-Reject-Accept sequence of mind changes in a suitable indexing.
2) $\mathcal{L}=\mathcal{H} \cup \mathcal{K}$, where for every $L \in \mathcal{H}$ and $L^{\prime} \in \mathcal{L}\left(L^{\prime} \subseteq L \Rightarrow L^{\prime}=L\right)$, and for every $L \in \mathcal{K}$ there is a finite $D_{L} \subseteq L$ such that for every $L^{\prime} \in \mathcal{L}\left(D_{L} \subseteq L^{\prime} \Rightarrow L^{\prime}=L\right)$.

Proof. Suppose that there is a learner $\mathcal{M}$ that Ex-learns $\mathcal{L}$ with the Accept-Reject-Accept sequence of mind changes in the indexing $\left\{L_{\alpha}\right\}_{\alpha \in I}$. Define $\mathcal{H}$ and $\mathcal{K}$ as follows:

$$
\mathcal{H}=\left\{L_{\alpha}: \text { every automaton output by } \mathcal{M} \text { on index } \alpha \text { and any text for } L_{\alpha} \text { accepts } \alpha\right\}
$$

and
$\mathcal{K}=\left\{L_{\alpha}:\right.$ there is a text $T$ for $L_{\alpha}$ such that the learner $\mathcal{M}$ has a Reject-Accept or Accept-Reject-Accept pattern of mind changes when it processes $\alpha$ and $T\}$.

Suppose that there are different $L_{\alpha} \in \mathcal{L}$ and $L_{\beta} \in \mathcal{H}$ such that $L_{\alpha} \subset L_{\beta}$. Run the learner $\mathcal{M}$ on index $\beta$ and some text for $L_{\alpha}$. There must be a step $s$ at which $\mathcal{M}$ outputs an automaton rejecting $\beta$. Let $\tau_{s}$ be the finite segment of the text seen by $\mathcal{M}$ at step $s$. Since $L_{\alpha} \subset L_{\beta}$, we
can extend $\tau_{s}$ to a text $T$ for $L_{\beta}$. Now $\mathcal{M}$ outputs an automaton rejecting $\beta$ when it processes $\beta$ and $T$. This contradicts our definition of $\mathcal{H}$.

Suppose that $L_{\alpha} \in \mathcal{K}$ and let $T$ be a text for $L_{\alpha}$ such that the learner $\mathcal{M}$ has a pattern of mind changes Reject-Accept or Accept-Reject-Accept when it processes $\alpha$ and $T$. Run $\mathcal{M}$ on the index $\alpha$ and the text $T$. Let $s$ be the step at which $\mathcal{M}$ changes its mind from Reject to Accept, and let $\tau_{s}$ be the finite segment of text $T$ seen by this step. Define $D_{\alpha}=\operatorname{content}\left(\tau_{s}\right)$.

Suppose that there is $L_{\beta} \in \mathcal{L}$ such that $L_{\beta} \neq L_{\alpha}$ and $D_{\alpha} \subseteq L_{\beta}$. Consider a text $T$ for $L_{\beta}$ that extends $\tau_{s}$. If we run $\mathcal{M}$ on index $\alpha$ and text $T$, then at step $s$ the learner will change its mind from Reject to Accept, and after that it will be accepting $\alpha$ forever. On the other hand, $\mathcal{M}$ must eventually reject $\alpha$ since $L_{\alpha} \neq \operatorname{content}(T)$. Therefore, $\mathcal{L}$ satisfies the condition 2) of the theorem.

Now suppose that the class $\mathcal{L}=\left\{L_{\alpha}\right\}_{\alpha \in I}$ satisfies condition 2) of the theorem. Let $M$ be a deterministic automaton that recognizes $\left\{(x, \alpha): x \in L_{\alpha}\right\}$. The set $J$ of new indices is defined as follows:

$$
\begin{aligned}
(\alpha, \beta, \gamma) \in J \Longleftrightarrow & \alpha \in I, \beta=0^{n} 1^{\omega} \text { for the minimal } n \text { such that for every } \alpha^{\prime} \in I \\
& \left(\left\{x \in L_{\alpha}:|x|<n\right\} \subseteq L_{\alpha^{\prime}} \Rightarrow L_{\alpha^{\prime}}=L_{\alpha}\right) \text {, and for every } k \\
& \gamma(k)=\left\{q \in Q_{M}: \exists x \in L_{\alpha}\left(|x| \leq k \text { and } \operatorname{St}_{M}(\otimes(x, \alpha), k)=q\right)\right\}
\end{aligned}
$$

Again, the set $J$ is automatic, and we can define a new automatic indexing $\left\{H_{\alpha, \beta, \gamma}\right\}_{(\alpha, \beta, \gamma) \in J}$ for the class $\mathcal{L}$ as follows

$$
H_{\alpha, \beta, \gamma}=L_{\alpha} .
$$

Let $A$ be an automaton that recognizes the set $J$, and let $Z$ be an automaton that rejects all $\omega$-strings. The learner $\mathcal{M}$ that Ex-learns $\mathcal{L}$ in this new indexing works as follows. At every step $s, \mathcal{M}$ reads the first $s$ inputs $x_{1}, \ldots, x_{s}$ from the input text. Then $\mathcal{M}$ outputs $A$ or $Z$ according to the following rules:

Case A: There is no $n \leq s$ such that $0^{n} 1 \subseteq \beta$. In this case $\mathcal{M}$ outputs $A$ if every $x_{i}$ which is different from \# belongs to $L_{\alpha}$ according to $\gamma$. Otherwise, $\mathcal{M}$ outputs $Z$.
Case B: There exists $n \leq s$ such that $0^{n} 1 \subseteq \beta$. In this case $\mathcal{M}$ outputs $A$ if

$$
\forall x\left(\left(|x|<n \text { and } x \in L_{\alpha} \text { according to } \gamma\right) \rightarrow x \in\left\{x_{1}, \ldots, x_{s}\right\}\right)
$$

Otherwise, $\mathcal{M}$ outputs $Z$.
It is clear that $\mathcal{M}$ has an Accept-Reject-Accept sequence of mind changes (or a subsequence thereof) for any index $(\alpha, \beta, \gamma) \in J$ and any text $T$ with $\operatorname{content}(T) \in \mathcal{L}$. If $\mathcal{M}$ always stays in Case A, then $H_{\alpha, \beta, \gamma}=L_{\alpha}$ is not in $\mathcal{K}$ and hence $L_{\alpha} \in \mathcal{H}$. By construction, $\mathcal{M}$ eventually accepts $(\alpha, \beta, \gamma)$ if and only if $\operatorname{content}(T) \subseteq L_{\alpha}$. But since $L_{\alpha} \in \mathcal{H}$, we have that content $(T) \subseteq L_{\alpha}$ implies content $(T)=L_{\alpha}$.

If at some step the learner $\mathcal{M}$ is in Case B , then $H_{\alpha, \beta, \gamma}=L_{\alpha} \in \mathcal{K}$. By construction, $\mathcal{M}$ eventually accepts $(\alpha, \beta, \gamma)$ if and only if $D_{\alpha} \subseteq \operatorname{content}(T)$, where $D_{\alpha}=\left\{x \in L_{\alpha}:|x|<n\right\}$. By the definition of $\beta, D_{\alpha} \subseteq \operatorname{content}(T)$ implies $L_{\alpha}=\operatorname{content}(T)$.

## 5 Blind Learning

Blind learning is distinguished from models of learning described in the previous sections in that a learner itself does not see the index tape. So the learner has to encode all the necessary
information into a sequence of automata which determines in the limit whether an index is correct or incorrect. In the case of behaviourally correct learning, this can be done by coding more and more finite information into such a sequence in a way that every incorrect index is eventually rejected (but the point from which on this happens depends on an index). In the case of explanatory learning, this turns out to be impossible. However if a class is countable, then we can simulate a traditional learner (for a countable class) and encode its output conjecture into an $\omega$-automaton which then checks whether the index provided is equivalent to the current output of the traditional learner. In some sense, this is the best that one can do, as all blind explanatorily learnable classes are countable.
Theorem 5.1. If a class $\mathcal{L}=\left\{L_{\alpha}\right\}_{\alpha \in I}$ satisfies Angluin's tell-tale condition, then $\mathcal{L}$ is BlindBC-learnable.

Proof. We describe an algorithm for a BlindBC-learner $\mathcal{M}$.
At step $s$, the learner reads the first $s$ inputs $x_{1}, \ldots, x_{s}$ from the input text. If every $x_{i}$ is equal to the pause symbol $\#$, then the learner outputs an automaton which accepts exactly the indices of $\emptyset$. Otherwise, let $z_{1}^{s}, \ldots, z_{t}^{s}$ be such that $z_{1}^{s}<_{l l e x} \cdots<_{l l e x} z_{t}^{s}$ and $\left\{z_{1}^{s}, z_{2}^{s}, \ldots, z_{t}^{s}\right\}=\left\{x_{1}, x_{2}, \ldots, x_{s}\right\}-\{\#\}$. For every $k$ with $1 \leq k \leq t$, let $A_{k}^{s}$ be an automaton such that

$$
\begin{aligned}
A_{k}^{s} \text { accepts } \alpha \Longleftrightarrow & \alpha \in I,\left(\left\{x_{1}, \ldots, x_{s}\right\}-\{\#\}\right) \subseteq L_{\alpha} \\
& \left\{x_{1}, \ldots, x_{s}\right\} \cap\left\{x: x \leq_{l l e x} z_{k}^{s}\right\}=L_{\alpha} \cap\left\{x: x \leq_{l l e x} z_{k}^{s}\right\} \\
& \text { and } L_{\alpha} \cap\left\{x: x \leq_{l l e x} z_{k}^{s}\right\} \text { is a tell-tale set for } L_{\alpha} .
\end{aligned}
$$

Such an $A_{k}^{s}$ exists since the property of being a tell-tale set is first-order definable from other automatic relations as described in the beginning of the proof of Theorem 3.1. Finally, in the end of step $s, \mathcal{M}$ outputs an automaton $A^{s}$ such that

$$
L\left(A^{s}\right)=\bigcup_{1 \leq k \leq t} L\left(A_{k}^{s}\right)
$$

To verify that the algorithm is correct, we need to show that for every input text $T$ with content $(T) \in \mathcal{L}$ and for every index $\alpha$
a) if $\alpha \in I$ and $L_{\alpha}=\operatorname{content}(T)$, then $A^{s}$ accepts $\alpha$ for almost all $s$,
b) if $\alpha \in I$ and $L_{\alpha} \neq \operatorname{content}(T)$ or if $\alpha \notin I$, then $A^{s}$ rejects $\alpha$ for almost all $s$.

First, suppose that $L_{\alpha}=\operatorname{content}(T)$. Since $\mathcal{L}$ satisfies Angluin's tell-tale condition, there are $s_{0}$ and $k$ such that for all $s \geq s_{0}$

$$
L_{\alpha} \cap\left\{x: x \leq_{l l e x} z_{k}^{s}\right\} \text { is a tell-tale set for } L_{\alpha} .
$$

Let $s_{1} \geq s_{0}$ be such that for every $s \geq s_{1}$

$$
\left\{x_{1}, \ldots, x_{s}\right\} \cap\left\{x: x \leq_{\text {llex }} z_{k}^{s}\right\}=L_{\alpha} \cap\left\{x: x \leq_{\text {llex }} z_{k}^{s}\right\} .
$$

Then, by definition, $A_{k}^{s}$ accepts $\alpha$ for all $s \geq s_{1}$. Therefore, $A^{s}$ accepts $\alpha$ for all $s \geq s_{1}$.
If $\alpha \notin I$, then every $A^{s}$ rejects $\alpha$ (note that our definitions of learning do not place any requirements on the learner when $\alpha \notin I$; this point is just for emphasis). So, suppose
that $\alpha \in I$ and $L_{\alpha} \neq \operatorname{content}(T)$. If $\exists x \in \operatorname{content}(T) \backslash L_{\alpha}$, then for some $s_{0}$ we have that $x \in\left\{x_{1}, \ldots, x_{s}\right\}$ for all $s \geq s_{0}$. Therefore, for all $s \geq s_{0},\left(\left\{x_{1}, \ldots, x_{s}\right\}-\{\#\}\right) \nsubseteq L_{\alpha}$ and $A^{s}$ rejects $\alpha$. Suppose that content $(T)$ is a proper subset of $L_{\alpha}$. Note that for every $s$ and $k$, if $L_{\alpha} \cap\left\{x: x \leq_{l l e x} z_{k}^{s}\right\}$ is a tell-tale set for $L_{\alpha}$, then

$$
\left\{x_{1}, \ldots, x_{s}\right\} \cap\left\{x: x \leq_{l l e x} z_{k}^{s}\right\} \neq L_{\alpha} \cap\left\{x: x \leq_{l l e x} z_{k}^{s}\right\} .
$$

Otherwise, content $(T)$ would be a proper subset of $L_{\alpha}$ containing a tell-tale set for $L_{\alpha}$, which is impossible. So, every $A_{k}^{s}$ and hence every $A^{s}$ rejects $\alpha$.

Theorem 5.2. For every class $\mathcal{L}=\left\{L_{\alpha}\right\}_{\alpha \in I}$, the following are equivalent

1) $\mathcal{L}$ is BlindEx-learnable.
2) $\mathcal{L}$ is BlindFEx-learnable.
3) $\mathcal{L}$ is at most countable and satisfies Angluin's tell-tale condition.

Proof. It is obvious that BlindEx-learnable class is BlindFEx-learnable. Suppose that $\mathcal{L} \in$ BlindFEx; then Fact 2.13 implies that $\mathcal{L}$ satisfies Angluin's tell-tale condition. We will show that $\mathcal{L}$ is countable.

Let $\mathcal{M}$ be a BlindFEx-learner for $\mathcal{L}$. Thus for every $L \in \mathcal{L}$ and every input text $T$ with $\operatorname{content}(T)=L$, the learner $\mathcal{M}$ outputs at least one automaton $A_{L}$ infinitely often. Since $\mathcal{M}$ is blind, $A_{L}$ must accept all indices $\alpha$ with $L_{\alpha}=L$ and reject all indices $\beta$ with $L_{\beta} \neq L$. If $L$ and $L^{\prime}$ are two different sets from $\mathcal{L}$, then $A_{L} \neq A_{L^{\prime}}$. Since there are only countably many different automata, the class $\mathcal{L}$ is at most countable.

Suppose that $\mathcal{L}$ is countable and satisfies Angluin's tell-tale condition. Consider the following equivalence relation on the set $I$ of indices for $\mathcal{L}$ :

$$
\alpha \sim \beta \quad \text { if and only if } \quad \forall x\left(x \in L_{\alpha} \leftrightarrow x \in L_{\beta}\right) .
$$

This equivalence relation is automatic since it is first-order definable from automatic relations. By assumption, it has countable index. As Bárány, Kaiser and Rubin [2] showed, every automatic equivalence relation of countable index has a countable automatic set of representatives. Let $J \subseteq I$ be a set of such representatives.

It is well-known that every automatic set of $\omega$-strings is a finite union of sets of the form $V \cdot U^{\omega}$, where $V$ and $U$ are automatic sets of finite strings (e.g., see [11]). If the set is countable, then $U$ contains only a single string $u$. Therefore, we have that $J=\bigcup_{i=1}^{k} V_{i} \cdot\left\{u_{i}\right\}^{\omega}$ for some automatic sets $V_{i}$ and finite strings $u_{i}$.

We now define an automatic indexing of the class $\mathcal{L}$ by finite strings. Let $\Sigma$ be the alphabet of the set $I$ and let $\Gamma$ be the alphabet of the sets $L_{\alpha}$. Consider an expanded alphabet $\Sigma^{\prime}=\Sigma \cup\{1, \ldots, k\}$ (we assume here that $\Sigma$ does not contain $\{1, \ldots, k\}$ ). A set $G$ of new indices will be

$$
G=\left\{v i: v \in V_{i} \text { and } i \in\{1, \ldots, k\}\right\} .
$$

Note that $G$ is automatic. The new indexing $\left\{H_{w}\right\}_{w \in G}$ of $\mathcal{L}$ is defined as follows: for every $v i \in G$, let

$$
H_{v i}=L_{v u_{i}^{\omega}} .
$$

We need to show that the relation $R=\left\{(x, w): x \in H_{w}\right\}$ is automatic. Let $M$ be a deterministic Muller automaton that recognizes the relation $\left\{(x, \alpha): x \in L_{\alpha}\right\}$. A finite automaton $A$ that recognizes $R$ can be defined informally as follows. On input $\otimes(x, v i), A$ simulates $M$ on the input $\otimes\left(x, v u_{i}^{\omega}\right)$. After processing its input, $A$ accepts it if and only if there is an accepting run of $M$ on $\otimes\left(x, v u_{i}^{\omega}\right)$ (that is, $A$ replaces $i$ by $u_{i}^{\omega}$ in its simulation). Thus,

$$
A \text { accepts } \otimes(x, v i) \Longleftrightarrow M \text { accepts } \otimes\left(x, v u_{i}^{\omega}\right)
$$

Below is a formal definition of $A$.
Suppose that $M=\left(Q^{M},(\Gamma \cup \Sigma \cup\{\#\})^{2}, q_{0}^{M}, T^{M}\right)$. For $i=1, \ldots, k$, let $u_{i}=u_{i, 1} \ldots u_{i, n_{i}}$, where $n_{i}$ is the length of $u_{i}$. Then $A=\left(Q,\left(\Gamma \cup \Sigma^{\prime} \cup\{\#\}\right)^{2}, q_{0}, T, F\right)$, where

1) $Q=\left\{(q, i, j): q \in Q^{M}, 0 \leq i \leq k\right.$, if $i=0$ then $j=0$, and if $i>0$ then $\left.1 \leq j \leq n_{i}\right\}$.
2) $q_{0}=\left(q_{0}^{M}, 0,0\right)$.
3) The transition function $T$ is defined as follows:
a) for every $a \in \Gamma \cup\{\#\}$ and $b \in \Sigma$,

$$
T((q, 0,0),(a, b))=\left(T^{M}(q,(a, b)), 0,0\right)
$$

b) for every $a \in \Gamma \cup\{\#\}$ and $i \in\{1, \ldots, k\}$,

$$
T((q, 0,0),(a, i))=\left(T^{M}\left(q,\left(a, u_{i, 1}\right)\right), i, 1\right)
$$

c) for every $a \in \Gamma, i \in\{1, \ldots, k\}$ and $j \in\left\{1, \ldots, n_{i}\right\}$,

$$
T((q, i, j),(a, \#))=\left(T^{M}\left(q,\left(a, u_{i, j+1}\right)\right), i, j+1\right)
$$

where it is assumed that $n_{i}+1=1$.
4) The final states are defined as

$$
\begin{aligned}
F=\{(q, i, j) \in Q: & i>0, \text { and there exists an accepting run of } M \\
& \text { on the string } \left.\otimes\left(\#^{\omega},\left(u_{i}^{[j]}\right)^{\omega}\right) \text { starting from } q\right\},
\end{aligned}
$$

where $u_{i}^{[j]}$ is the cyclic shift of $u_{i}$ by $j$ symbols, i.e.,

$$
u_{i}^{[j]}=u_{i, j+1} \ldots u_{i, n_{i}} u_{i, 1} \ldots u_{i, j} .
$$

Note that the final states $F$ of the automaton $A$ can be computed effectively.
Since $\left\{H_{w}\right\}_{w \in G}$ is automatic and satisfies Angluin's tell-tale condition, there is a recursive learner $\mathcal{M}^{\prime}$ such that, on any input text $T$ for $H_{w}$ (where $w \in G$ ), $\mathcal{M}^{\prime}$ converges on $T$ to an index $w^{\prime}$ such that $H_{w^{\prime}}=H_{w}$ (see [10]; this is traditional Ex-learning of countable automatic families satisfying Angluin's tell-tale condition). For every $w \in G$, let $A_{w}$ be an automaton such that

$$
L\left(A_{w}\right)=\left\{\alpha \in I: \forall x\left(x \in L_{\alpha} \leftrightarrow x \in H_{w}\right)\right\} .
$$

Such an $A_{w}$ exists since $L\left(A_{w}\right)$ is first-order definable from automatic relations. Now the BlindEx-learner $\mathcal{M}$ for the class $\mathcal{L}=\left\{L_{\alpha}\right\}_{\alpha \in I}$ acts as follows: on an input text $T$ for some $L \in \mathcal{L}$, it simulates the work of $\mathcal{M}^{\prime}$, and whenever $\mathcal{M}^{\prime}$ outputs an index $w \in G$, the learner $\mathcal{M}$ outputs the automaton $A_{w}$.

Since $\mathcal{M}^{\prime}$ converges to an index $w$ such that $H_{w}=\operatorname{content}(T)$, we have that $\mathcal{M}$ converges to the automaton $A_{w}$ such that $L\left(A_{w}\right)=\left\{\alpha \in I: L_{\alpha}=\operatorname{content}(T)\right\}$. Therefore, the class $\mathcal{L}$ is BlindEx-learnable.
The following corollary summarizes the main results from this and the previous sections.
Corollary 5.3. For every automatic class $\mathcal{L}$, the following are equivalent:

1) $\mathcal{L}$ satisfies Angluin's tell-tale condition.
2) $\mathcal{L}$ is BC-learnable.
3) $\mathcal{L}$ is BlindBC-learnable.
4) $\mathcal{L}$ is FEx-learnable.
5) $\mathcal{L}$ is $\mathbf{E x}$-learnable in a suitable indexing.

Proof. The implications 3) $\Rightarrow 2$ ) and 4$) \Rightarrow 2$ ) are trivial; 2) $\Rightarrow 1$ ) and 5) $\Rightarrow 1$ ) follow from Fact $2.13 ; 1) \Rightarrow 3$ ) follows from Theorem $5.1 ; 1) \Rightarrow 4$ ) follows from Theorem 3.1 ; and 1 ) $\Rightarrow 5$ ) follows from Theorem 4.1.

## 6 Partial Identification

Partial identification is, in the traditional setting of inductive inference, a learning criterion where the learner outputs on every text of an r.e. language infinitely many (not necessarily distinct) hypotheses such that exactly one hypothesis occurs infinitely often and that hypothesis is correct. There is a recursive learner succeeding on all r.e. sets, hence this concept is omniscient in the traditional setting [13]. Also in our model, every automatic class is partially identifiable.

Theorem 6.1. Every automatic class with any given automatic indexing is Part-learnable.
Proof. Consider an automatic indexing $\left\{L_{\alpha}\right\}_{\alpha \in I}$ for a class $\mathcal{L}$. Let $M$ be an automaton recognizing the relation ' $x \in L_{\alpha}$ ', and let $\equiv_{M, \alpha}$ and $\equiv_{M, \alpha, s}$ be the relations defined in the proof of Theorem 3.1. For every pair of strings $(x, y)$ with $x<_{l l e x} y$, let $Z_{(x, y)}$ be an automaton that rejects all inputs. For every $k \geq 1$ and every tuple $\left(x_{1}, \ldots, x_{k}\right)$ with $x_{1}<_{\text {llex }} \cdots<_{\text {llex }} x_{k}$, let $A_{\left(x_{1}, \ldots, x_{k}\right)}$ be an automaton that accepts an $\omega$-string $\alpha$ if and only if

$$
\forall y\left(y \in L_{\alpha} \Longleftrightarrow y \equiv_{M, \alpha} x_{i} \text { for some } i \in\{1, \ldots, k\}\right)
$$

We assume that all the automata defined above are different from each other. Extend the ordering $\leq_{l l e x}$ to pairs of strings as follows: $\left(x^{\prime}, y^{\prime}\right) \leq_{l l e x}(x, y)$ if and only if one of the following conditions is satisfied:

1) $\max \left\{\left|x^{\prime}\right|,\left|y^{\prime}\right|\right\}<\max \{|x|,|y|\}$,
2) $\max \left\{\left|x^{\prime}\right|,\left|y^{\prime}\right|\right\}=\max \{|x|,|y|\}$ and $x^{\prime}<_{\text {llex }} x$,
3) $\max \left\{\left|x^{\prime}\right|,\left|y^{\prime}\right|\right\}=\max \{|x|,|y|\}, x=x^{\prime}$ and $y^{\prime} \leq_{\text {llex }} y$.

Let $\mathcal{M}$ be a learner constructed to satisfy the following properties:

1) $\mathcal{M}$ outputs the automaton $Z_{(x, y)}$ on index $\alpha$ and text $T$ at least $n$ times if and only if there exists $s \geq n$ such that
$-x<_{l l e x} y$ and $x \equiv_{M, \alpha, s} y$,
$-\left|\{x, y\} \cap \operatorname{content}\left(\tau_{s}\right)\right|=1$, where $\tau_{s}$ is the initial segment of $T$ of length $s$,

- there is no $\left(x^{\prime}, y^{\prime}\right)<_{\text {llex }}(x, y)$ for which the above two properties hold.

2) $\mathcal{M}$ outputs the automaton $A_{\left(x_{1}, \ldots, x_{k}\right)}$ on index $\alpha$ and text $T$ at least $n$ times if and only if there exists $s \geq n$ such that

- for every $i \in\{1, \ldots, k\}$ and every $y<_{\text {llex }} x_{i}$ we have that $y \not \equiv_{M, \alpha, s} x_{i}$,
$-\left\{x_{1}, \ldots, x_{k}\right\} \subseteq \operatorname{content}\left(\tau_{s}\right)$,
- for every $z \notin\left\{x_{1}, \ldots, x_{k}\right\}$ with $|z| \leq n$, if $\forall y<_{l l e x} z\left(y \not \equiv_{M, \alpha, s} z\right)$ then $z \notin$ content $\left(\tau_{s}\right)$,
- for every $x, y$ such that $\max \{|x|,|y|\} \leq n$, if $x<_{l l e x} y$ and $x \equiv_{M, \alpha, s} y$ then $\mid\{x, y\} \cap$ $\operatorname{content}\left(\tau_{s}\right) \mid \neq 1$.
It is not hard to verify that if the learner $\mathcal{M}$ satisfies the above properties, then for any $\alpha$ and $T$ :
a) $\mathcal{M}$ outputs $Z_{(x, y)}$ infinitely often on $\alpha$, $T$ if and only if $(x, y)$ is the $\leq_{l l e x}$ least pair such that $x<_{l l e x} y, x \equiv_{M, \alpha} y$ and $|\{x, y\} \cap \operatorname{content}(T)|=1$.
b) $\mathcal{M}$ outputs $A_{\left(x_{1}, \ldots, x_{k}\right)}$ infinitely often on $\alpha, T$ if and only if $x_{1}, \ldots, x_{k}$ are exactly those $\leq_{l l e x}$ least representatives of equivalence classes of $\equiv_{M, \alpha}$ which belong to content $(T)$, and there is no $(x, y)$ such that $x<_{l l e x} y, x \equiv_{M, \alpha} y$ and $|\{x, y\} \cap \operatorname{content}(T)|=1$.
Now, if $\operatorname{content}(T)$ is not equal to the union of equivalence classes of $\equiv_{M, \alpha}$, then $\mathcal{M}$ outputs only $Z_{(x, y)}$ infinitely often for some $(x, y)$, and it rejects the index $\alpha$. Otherwise, $\mathcal{M}$ outputs only $A_{\left(x_{1}, \ldots, x_{k}\right)}$ infinitely often, where $x_{1}, \ldots, x_{k}$ are the $\leq_{l l e x}$ least representatives of the equivalence classes belonging to content $(T)$. By definition, $A_{\left(x_{1}, \ldots, x_{k}\right)}$ accepts index $\alpha$ if and only if $L_{\alpha}$ is the union of the equivalence classes of $x_{1}, \ldots, x_{k}$. The latter is equivalent to $L_{\alpha}=\operatorname{content}(T)$ by the property b) above.

Theorem 6.2. A class $\mathcal{L}=\left\{L_{\alpha}\right\}_{\alpha \in I}$ is in BlindPart if and only if it is at most countable.
Proof. First, we show that if $\mathcal{L} \in$ BlindPart, then it is at most countable. Let $\mathcal{M}$ be a BlindPart-learner for $\mathcal{L}$. Fix a set $L \in \mathcal{L}$ and some text $T$ for $L$. The learner $\mathcal{M}$ outputs exactly one automata infinitely often when processing the text $T$. Let $A$ be such an automaton. Since $\mathcal{M}$ is blind, $A$ must accept only those $\alpha$ for which $L_{\alpha}=L$. Since there are only countably many different automata, the class $\mathcal{L}$ is at most countable.

To prove the other implication, assume that $\mathcal{L}$ is at most countable. In this case we can construct a new automatic indexing $\left\{H_{w}\right\}_{w \in G}$ for $\mathcal{L}$ by finite strings as shown in the proof of Theorem 5.2. Moreover, we can choose this indexing to be one-to-one. For every $w \in G$, let $A_{w}$ be an automaton that recognizes the set $\left\{\alpha \in I: L_{\alpha}=H_{w}\right\}$.
The BlindPart-learner $\mathcal{M}$ works as follows. At every step $s, \mathcal{M}$ reads the first $s$ inputs $x_{1}, \ldots, x_{s}$ from the input text $T$, and for every $w \in G$ with $|w| \leq s$, it computes the coincidence between $\left\{x_{1}, \ldots, x_{s}\right\}$ and $H_{w}$ at step $s$, that is,

$$
\begin{gathered}
C(w, s)=\max \{n: n \leq s \text { and for every string } x \text { with }|x| \leq n \\
\left.\left(x \in\left\{x_{1}, \ldots, x_{s}\right\} \Longleftrightarrow x \in H_{w}\right)\right\} .
\end{gathered}
$$

If there exists a $w \in G$ with $|w| \leq s$ and $C(w, s)>C(w, s-1)$, then $\mathcal{M}$ outputs $A_{w}$ for the $\leq_{l l e x}$ least such $w$. Otherwise, $\mathcal{M}$ does not produce an output at step $s$.

To verify that the algorithm is correct, let $T$ be a text for a set $L \in \mathcal{L}$ and let $w_{0}$ be an index such that $H_{w_{0}}=L$. Since the indexing $\left\{H_{w}\right\}_{w \in G}$ is one-to-one, we have that $\lim _{s} C\left(w_{0}, s\right)=$ $\infty$, but for every $w^{\prime} \neq w_{0}, \lim _{s} C\left(w^{\prime}, s\right)<\infty$. Thus, every $A_{w^{\prime}}$ with $w^{\prime} \neq w_{0}$ will be output only finitely often. Let $s_{0}$ be a step by which all $C\left(w^{\prime}, s\right)$ with $w^{\prime}<_{l l e x} w_{0}$ have reached their limit. Then at every step $s \geq s_{0}$ such that $C\left(w_{0}, s\right)>C\left(w_{0}, s-1\right), \mathcal{M}$ outputs $A_{w_{0}}$. Therefore, $A_{w_{0}}$ is output infinitely often and by definition $L\left(A_{w_{0}}\right)=\left\{\alpha \in I: L_{\alpha}=H_{w_{0}}=L\right\}$.
